

# Visual Computing

## 2024/2025

Class 2

Visual Perception

# Today's Agenda

- A first (brief) look at Computer Graphics
- Why talk about Visual Perception?
- Visual Perception

# What is Computer Graphics?

# What is Computer Graphics?

The technology with which **pictures** are

- Captured or generated, and presented
- Manipulated and / or processed
- Merged with other, non-graphical application data

It includes:

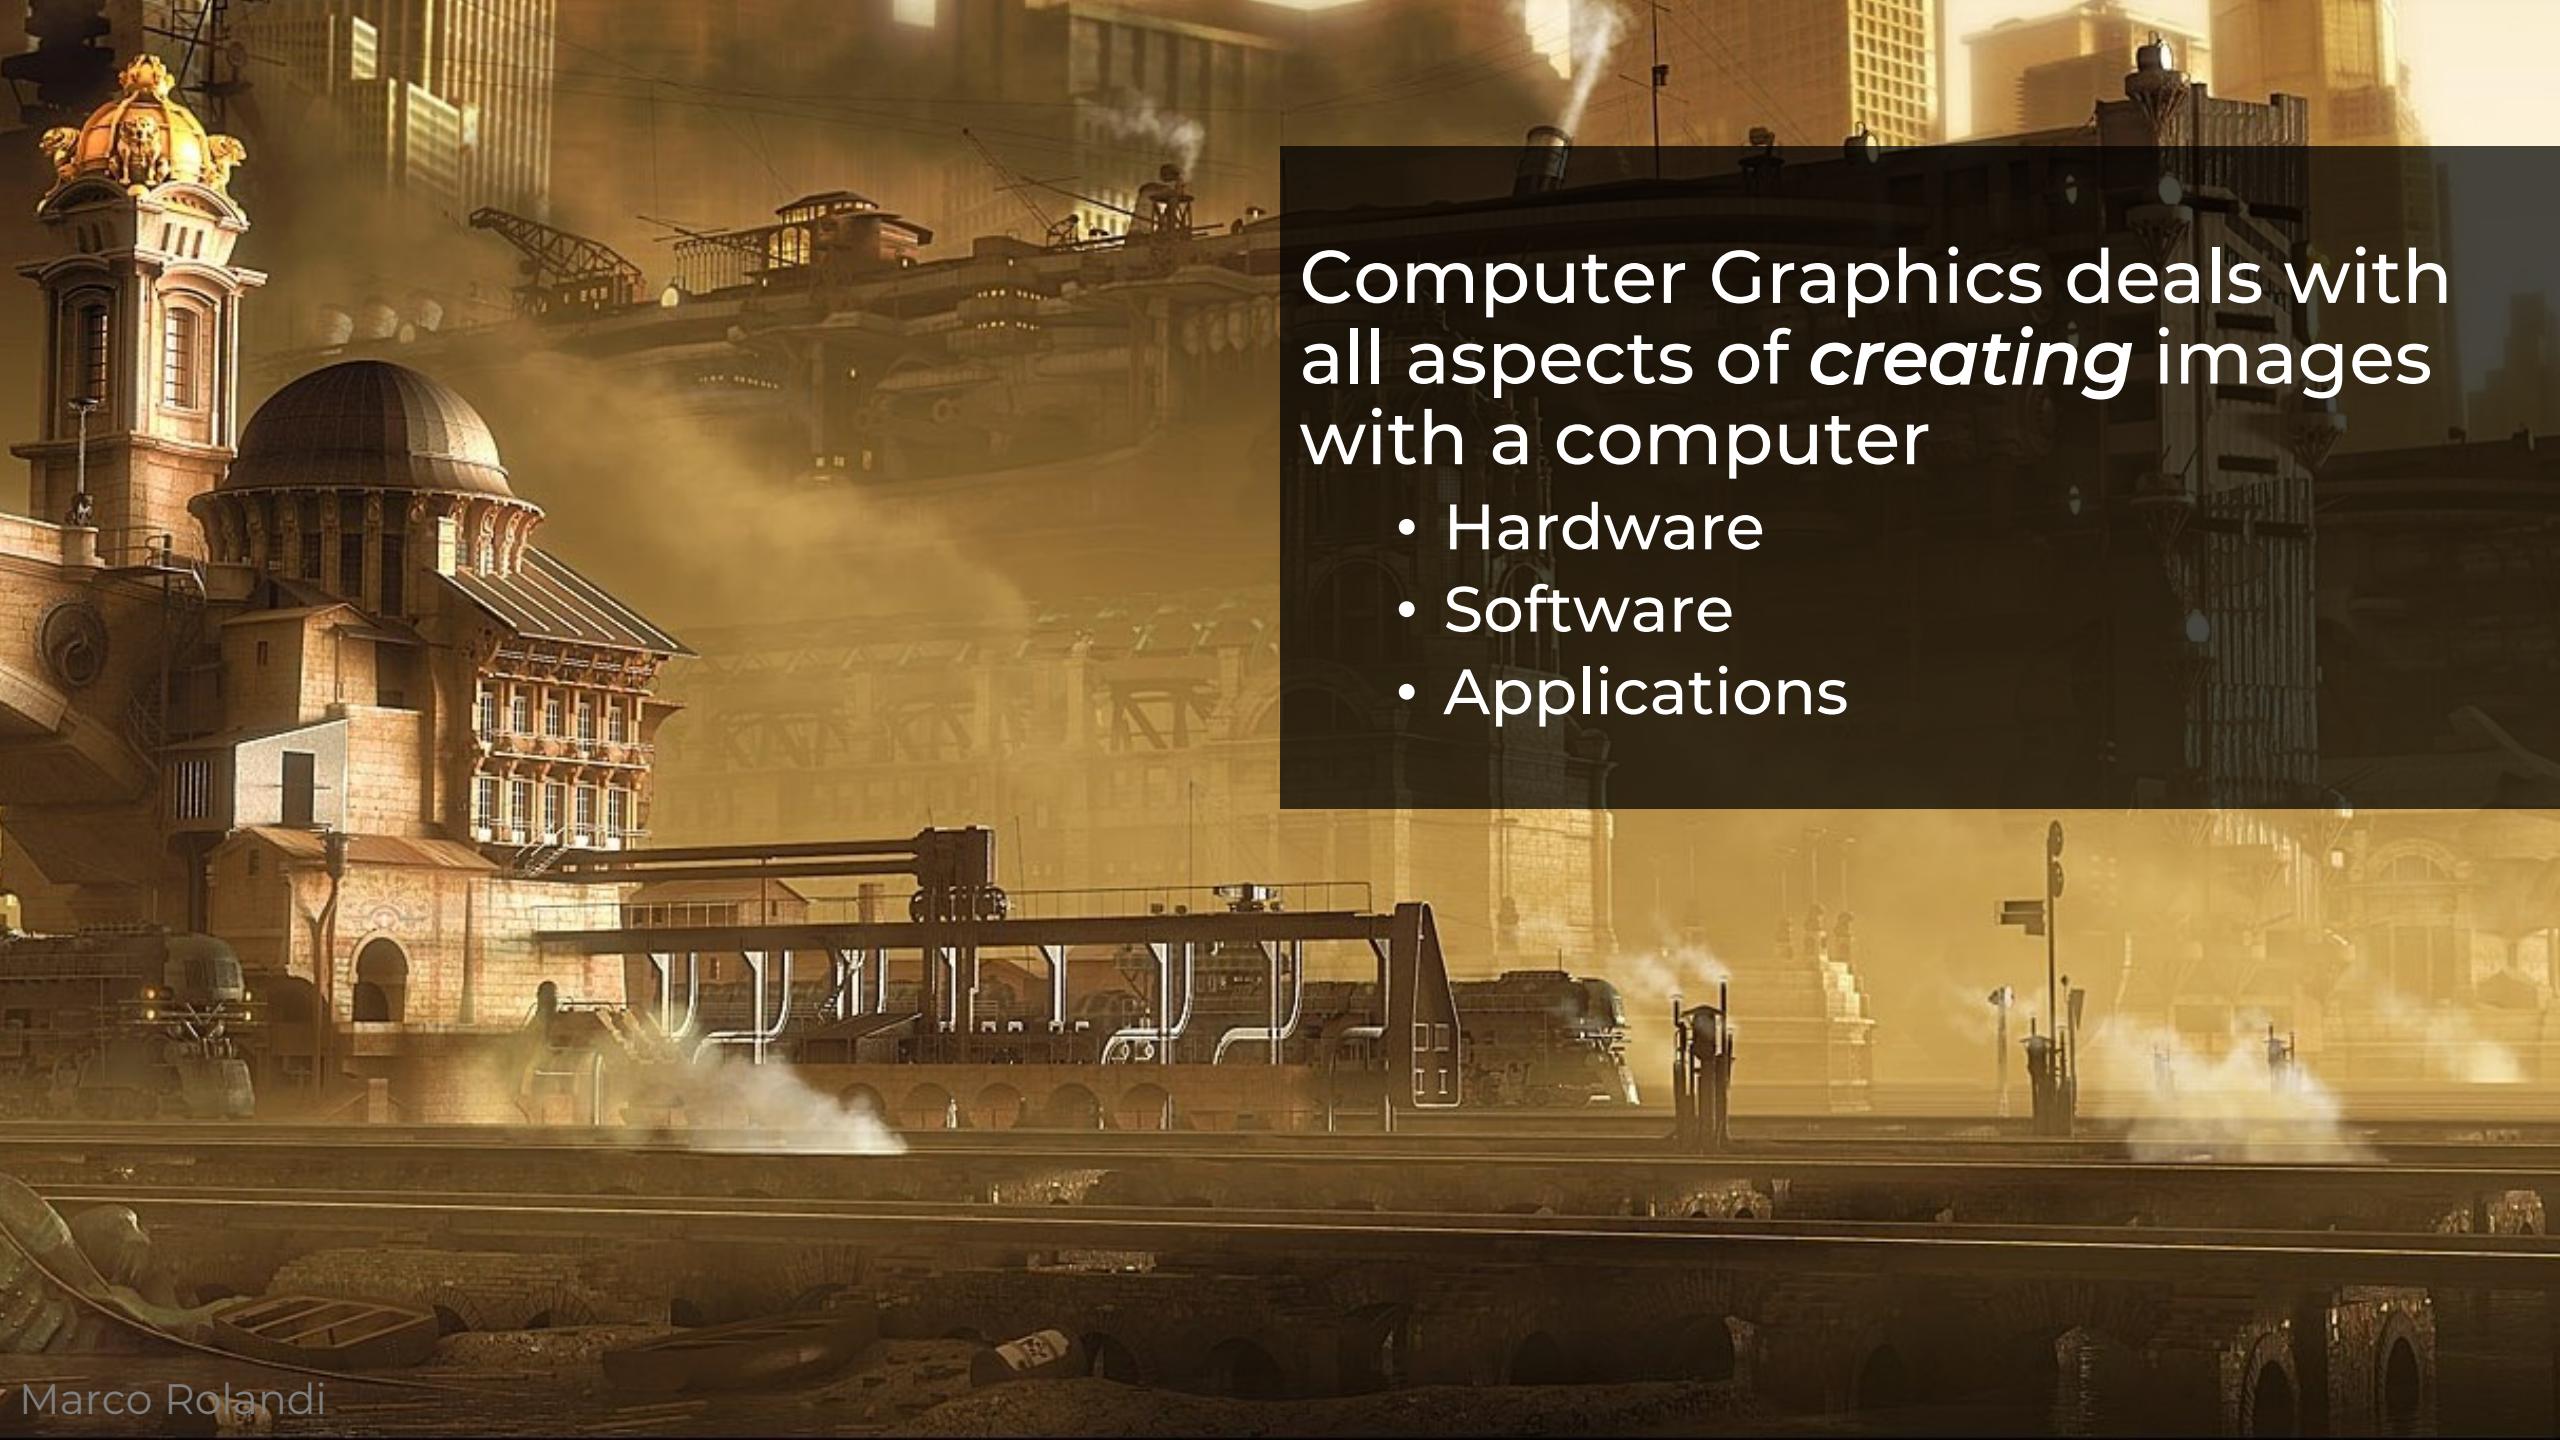

- Integration with other kinds of data – Multimedia
- Advanced dialogue and interactive technologies

# What is Computer Graphics?

Computer graphics generally means **creation, storage** and **manipulation** of **models** and **images**

Such models come from a diverse and expanding set of fields

- Physical, biological, mathematical, artistic, and conceptual / abstract structures

A detailed steampunk-style illustration of a city at night. The scene features a mix of Victorian-era buildings with ornate facades and domes, and industrial structures like smokestacks and pipes. A steam train is visible in the foreground, emitting a large plume of white smoke. The sky is filled with a hazy, golden light from street lamps and building windows, creating a warm, atmospheric glow.

Computer Graphics deals with  
all aspects of *creating* images  
with a computer

- Hardware
- Software
- Applications

Why talk about  
Visual Perception?

# Visual Perception and Computer Graphics

# We'll go for a hike and will see the mountain... ...from afar

A photograph of a man and a woman hiking in a mountainous area. The man, on the left, wears a blue long-sleeved shirt, black shorts, a green headband, and a yellow and black backpack. The woman, on the right, wears a red long-sleeved shirt, black shorts, and a black backpack. They are walking on a grassy hillside with mountains in the background under a clear sky.

This is not intended as a very detailed account of visual perception, but a first glimpse at the range of aspects that may constitute grounds for understanding its importance

# The Visual System

Eye

Optic  
nerve

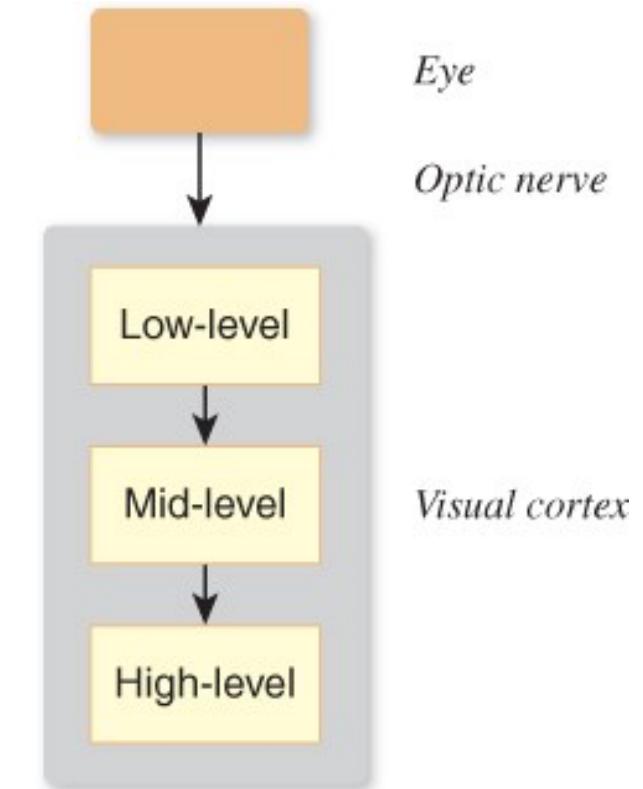

Visual  
cortex

# The Visual Cortex

First stages (“early vision”) deal with low-level processing

- Sharp contrasts in brightness
- Changes in colour, orientation, spatial frequency

Detection is “local”, i.e., for regions that are close

# The Visual Cortex

The remaining levels of processing deal with:

- Detecting motion, objects, shapes
- Handling attention
- Eye control (e.g., to act co-ordinately to follow an object)

While we represent it as sequential it is substantially parallel processing

# The visual system's versatility

You can easily spot the black dot  
on this slide

And you can watch the movies  
on the right (full of grain)  
ignoring most of the noise  
beyond the central scene

# To Eat and Not to be Eaten

Evolutionary needs modelled our visual system

Visual System is good at:

- Detecting motion and colour similarity under different lighting conditions
- Determining depth at close range: hand-eye coordination

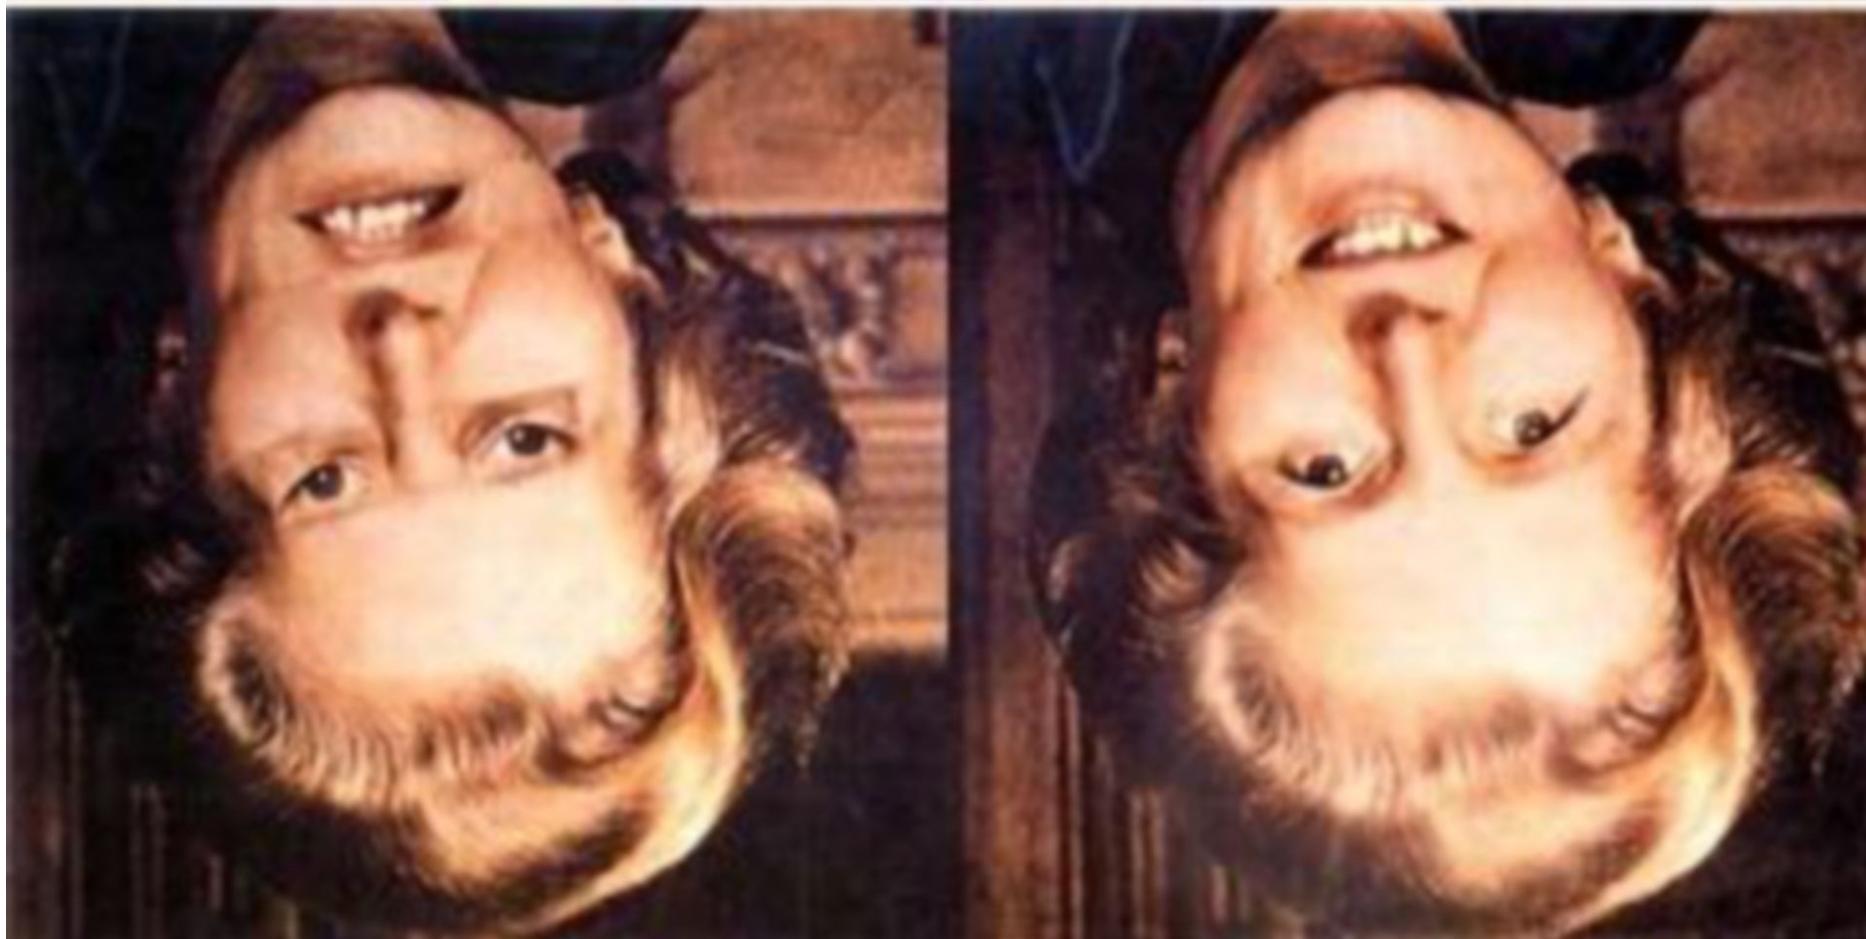

Spot something?

Spot something?

# There is a lot going on at the visual cortex

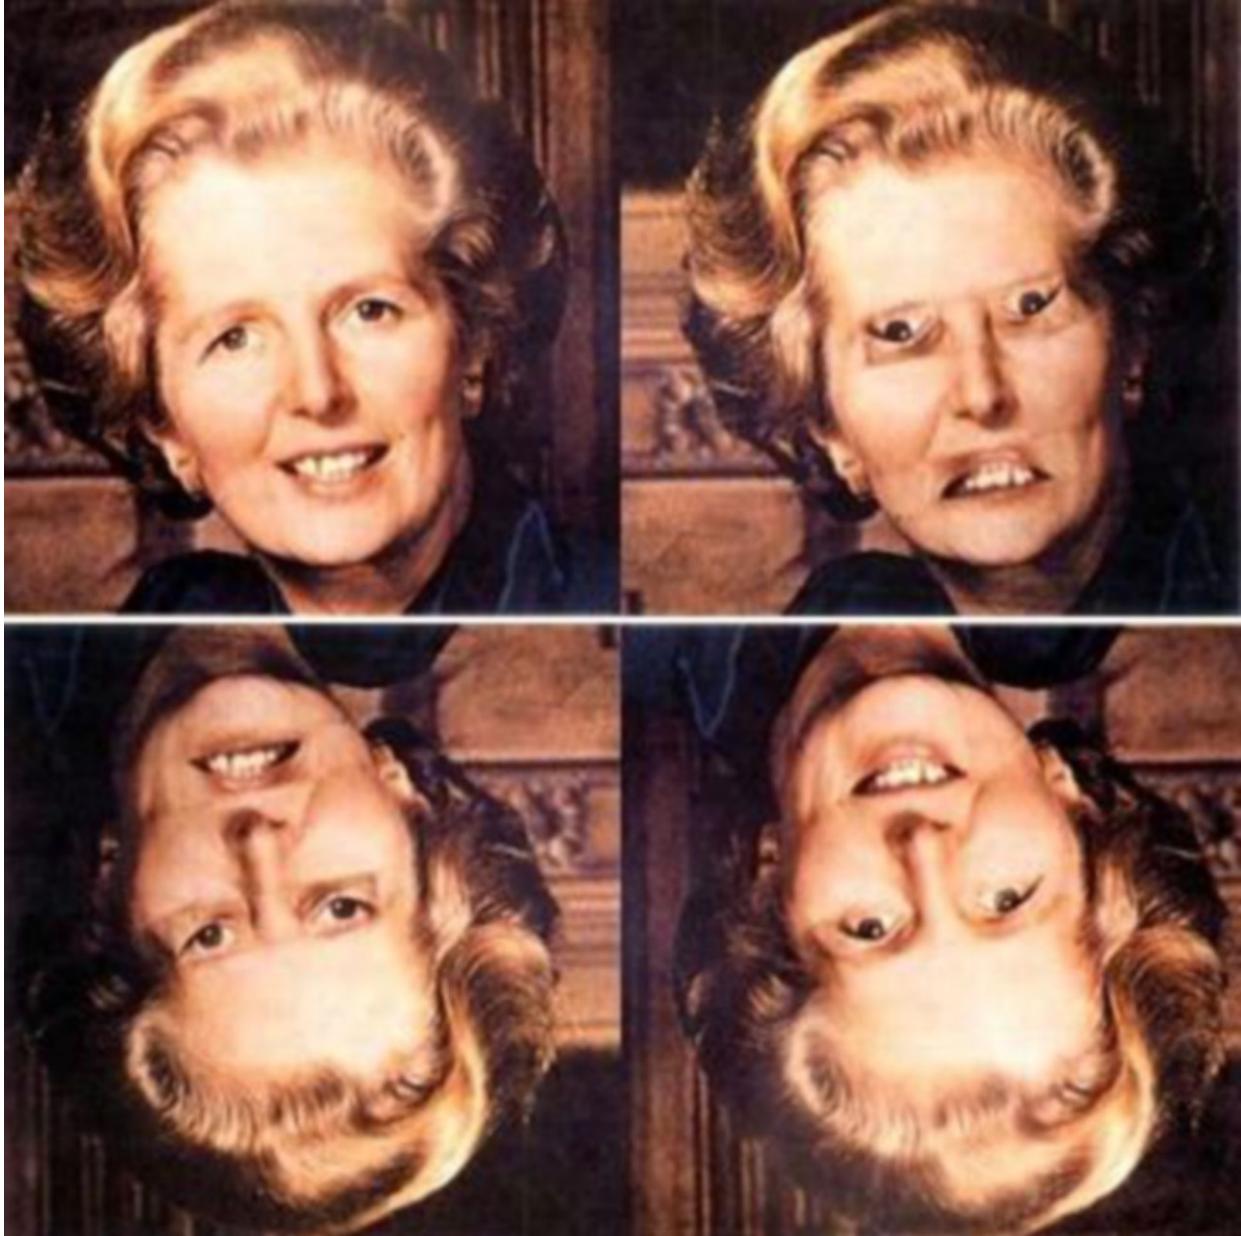

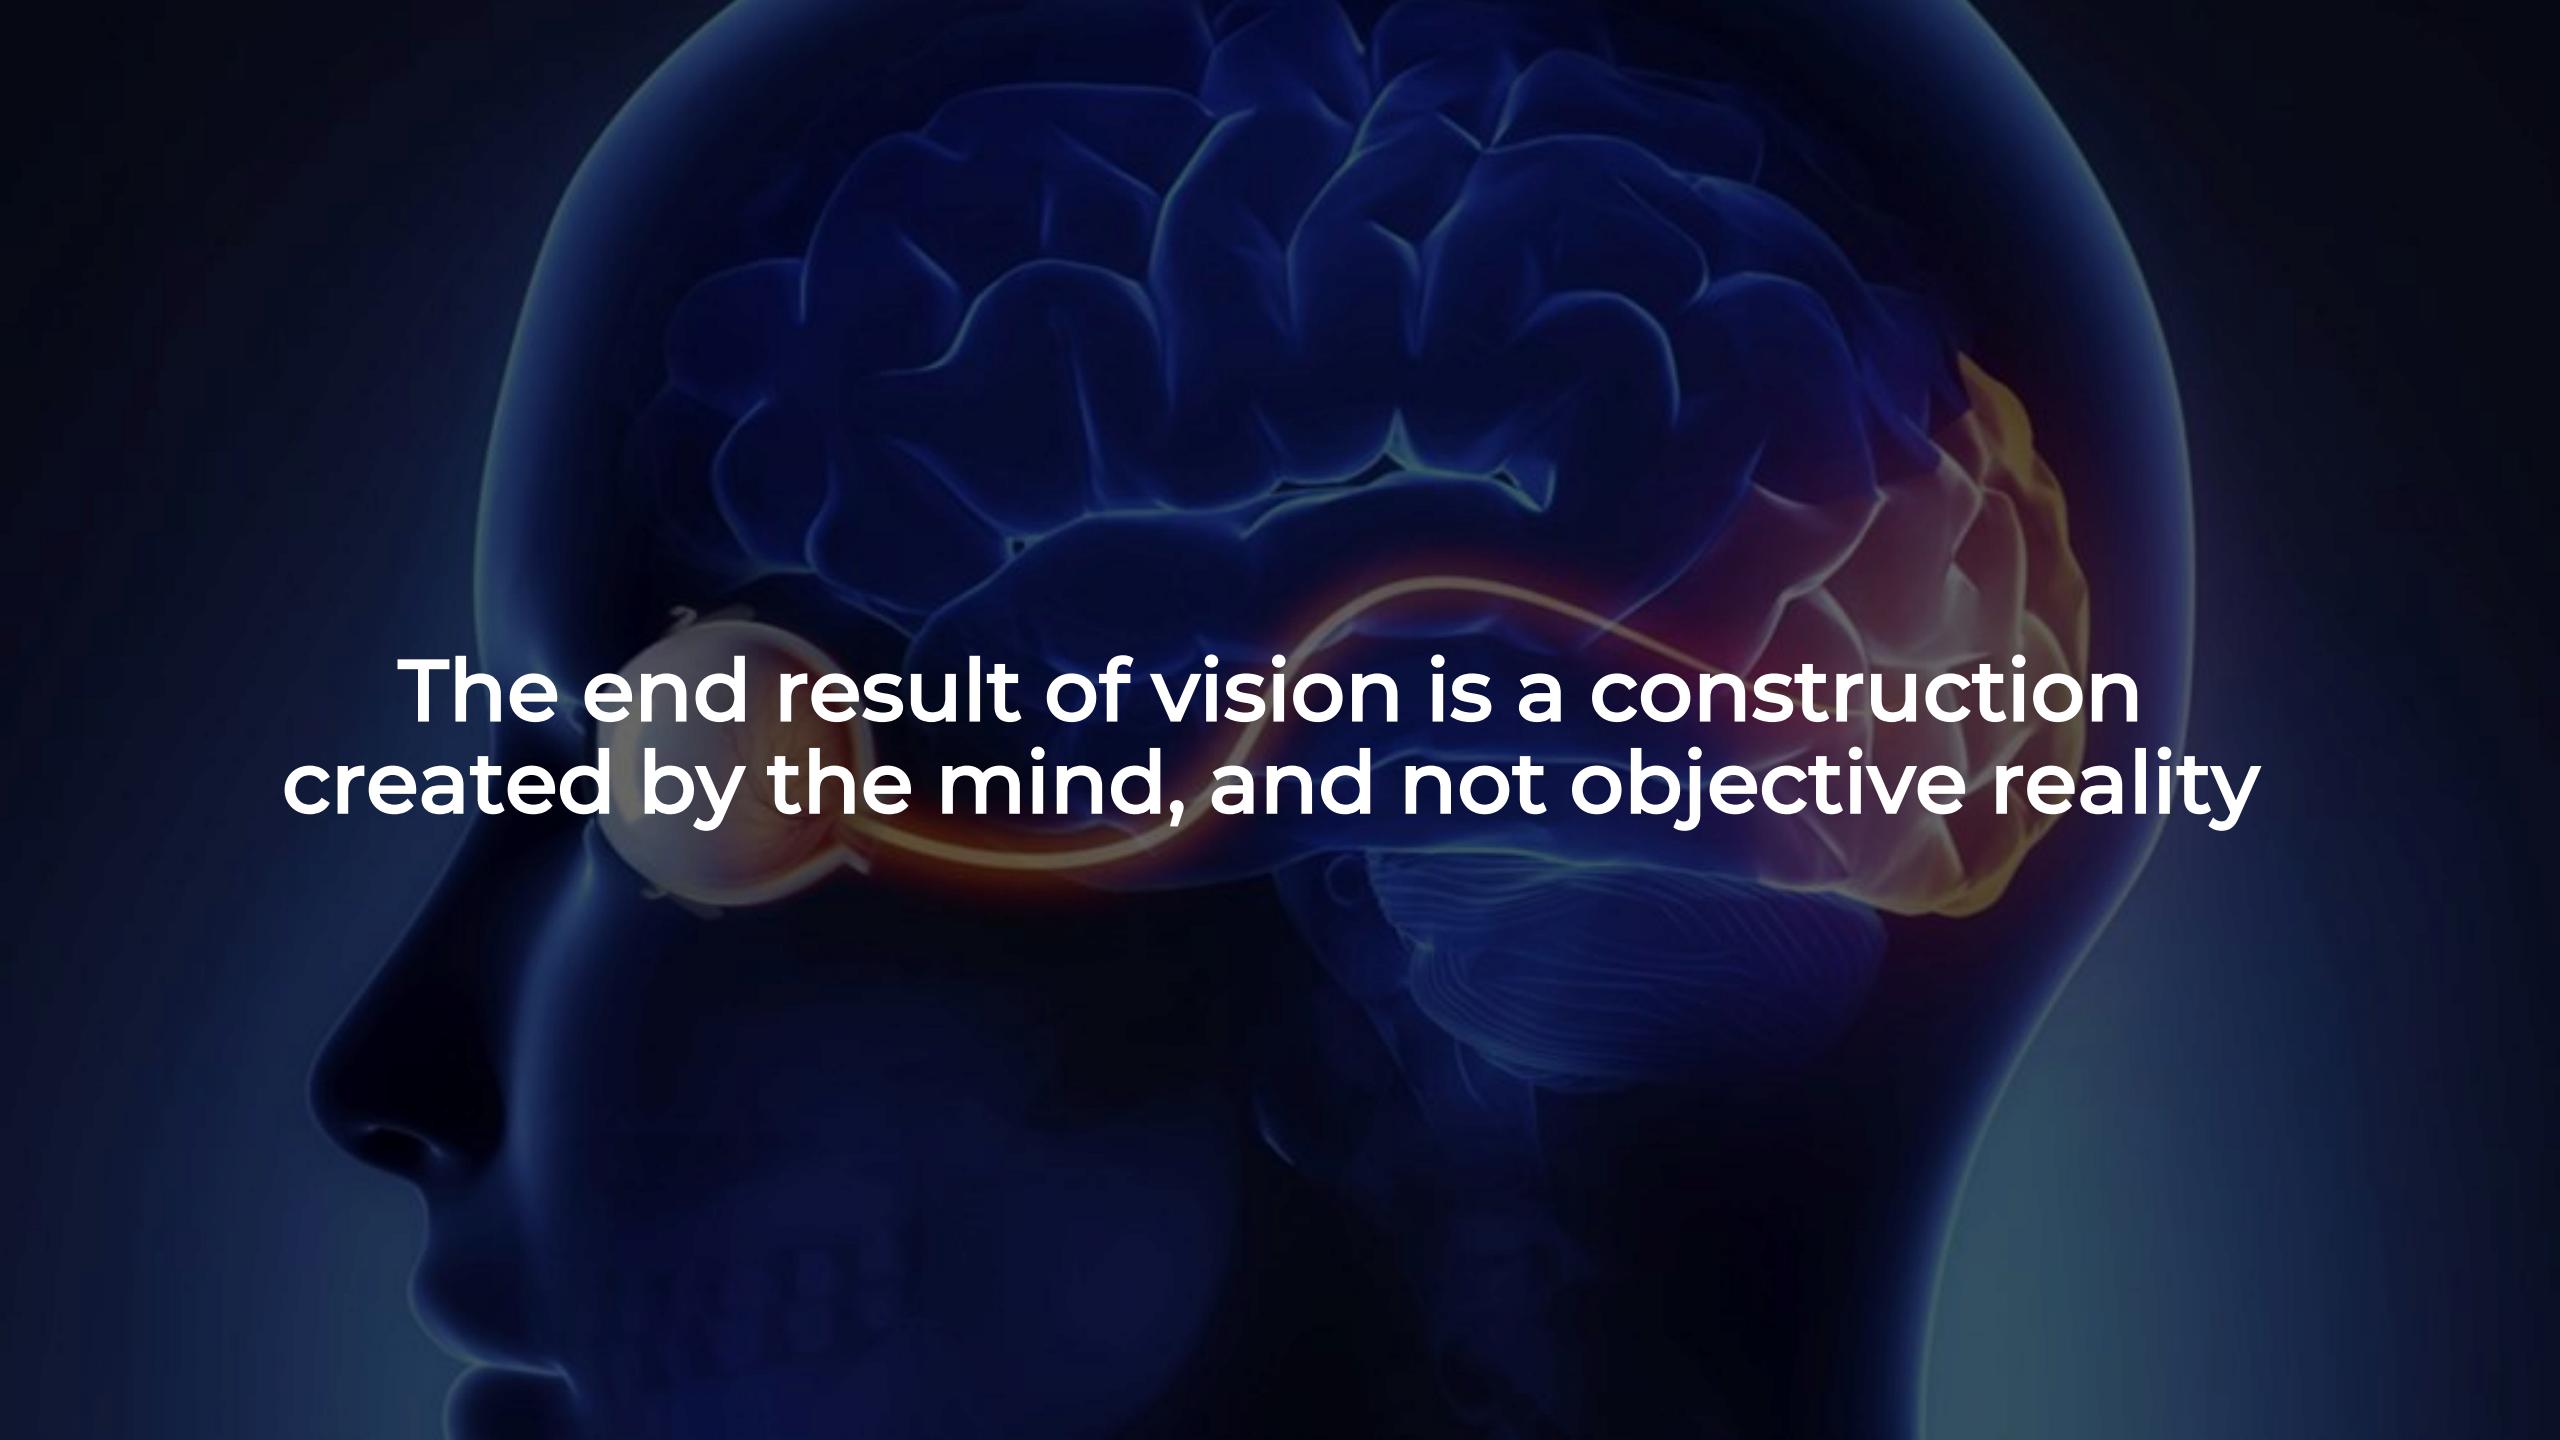

# The Thatcher Effect

The Visual System is also very good at processing faces

But that does not work well if they are upside-down

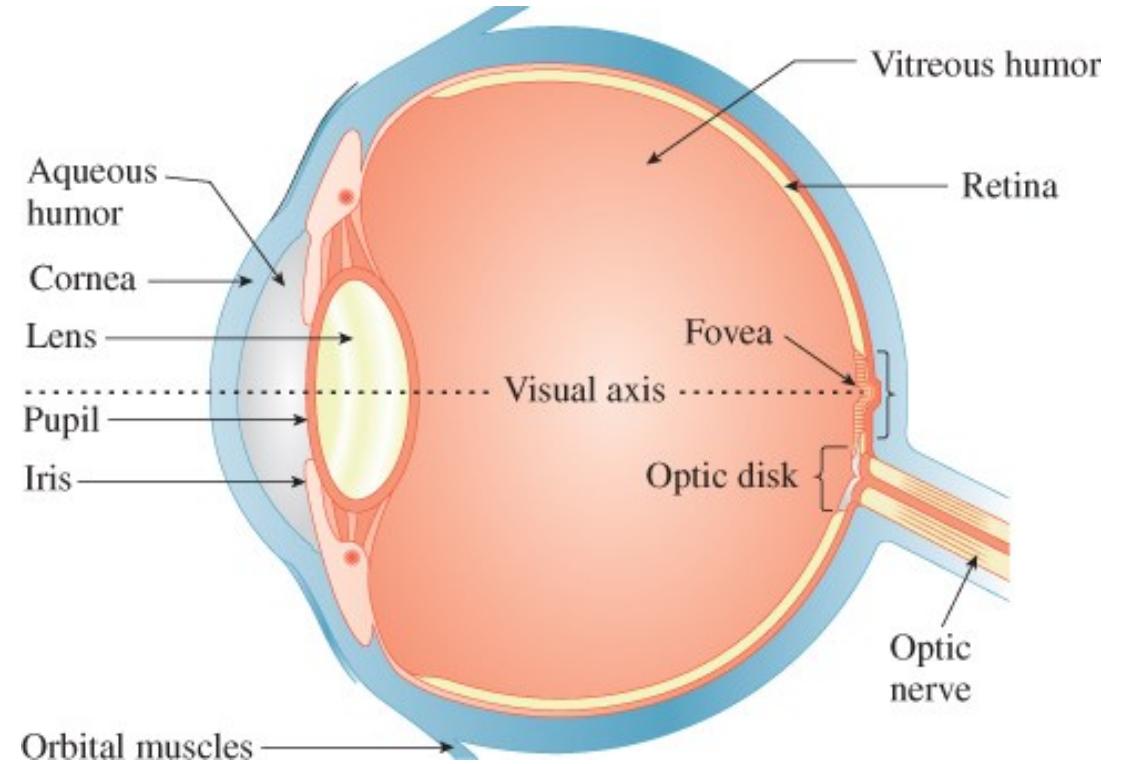

Modelling faces for a game is important and can pose issues if not done properly

A stylized profile of a human head facing left. The interior of the head is visible, showing a glowing blue brain with yellow highlights in the eye sockets. The overall color palette is dark, with deep blues and blacks, creating a mysterious and scientific atmosphere.

**The end result of vision is a construction  
created by the mind, and not objective reality**

# Eye Physiology

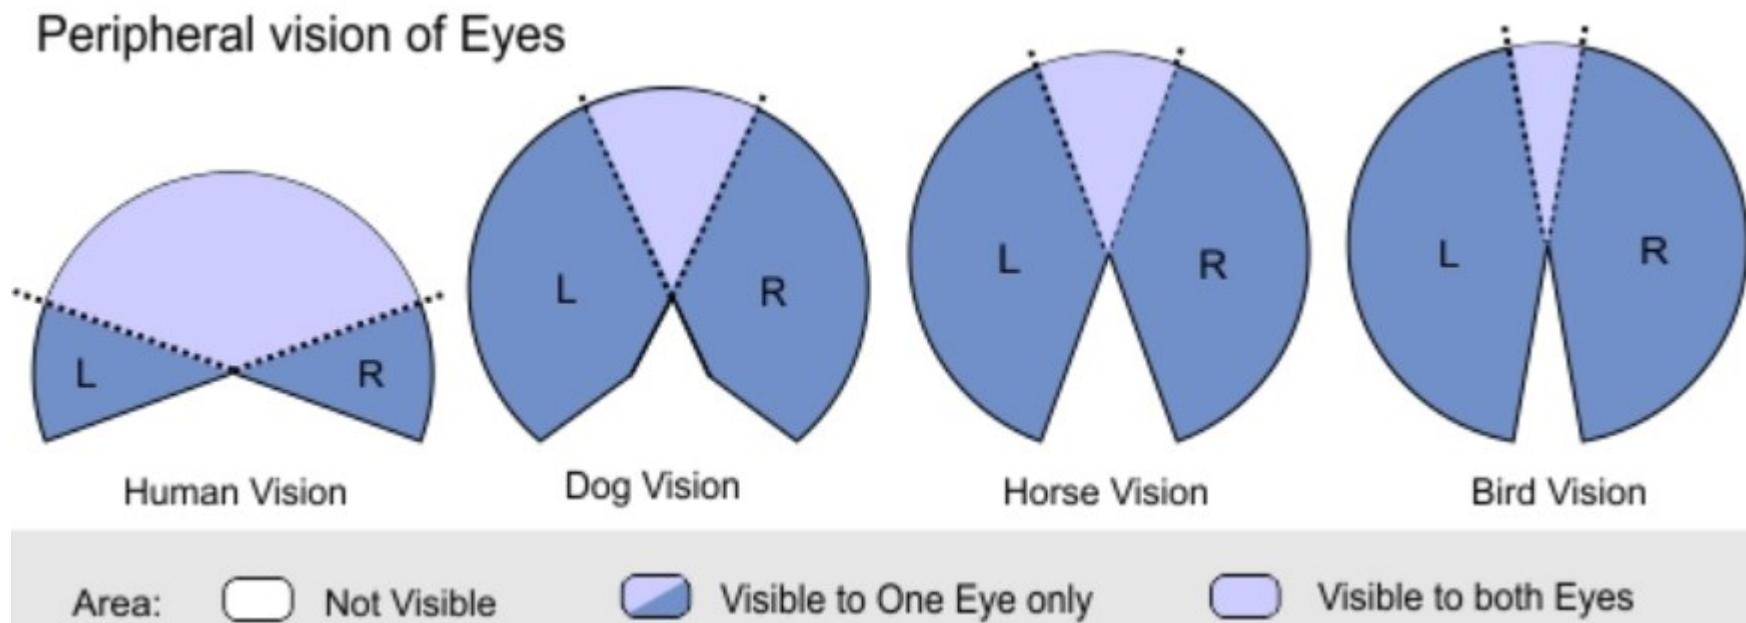

# Field of view

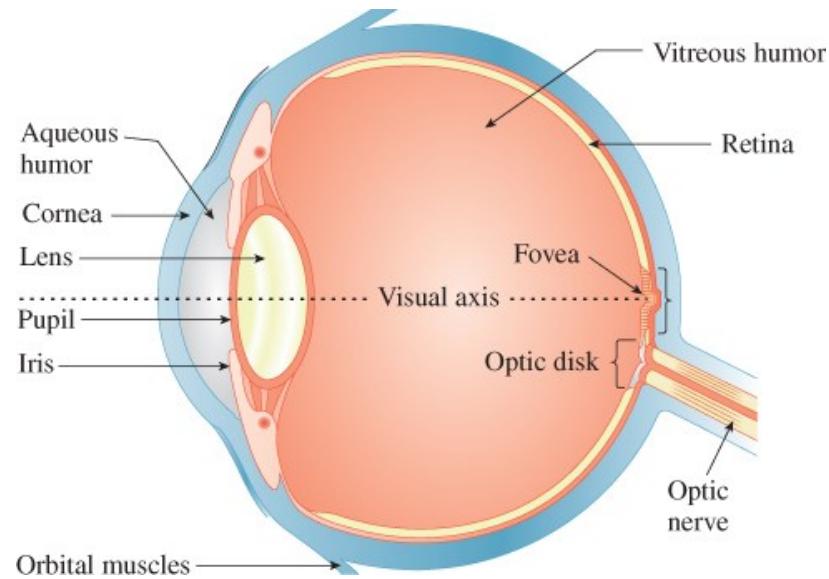

Each eye:  $160^\circ$ horizontal (H) by  $135^\circ$ vertical (V).

With binocular viewing: approximately  $200^\circ$ H by  $135^\circ$ V

Overlap: approximately  $120^\circ$ H by  $135^\circ$ V.

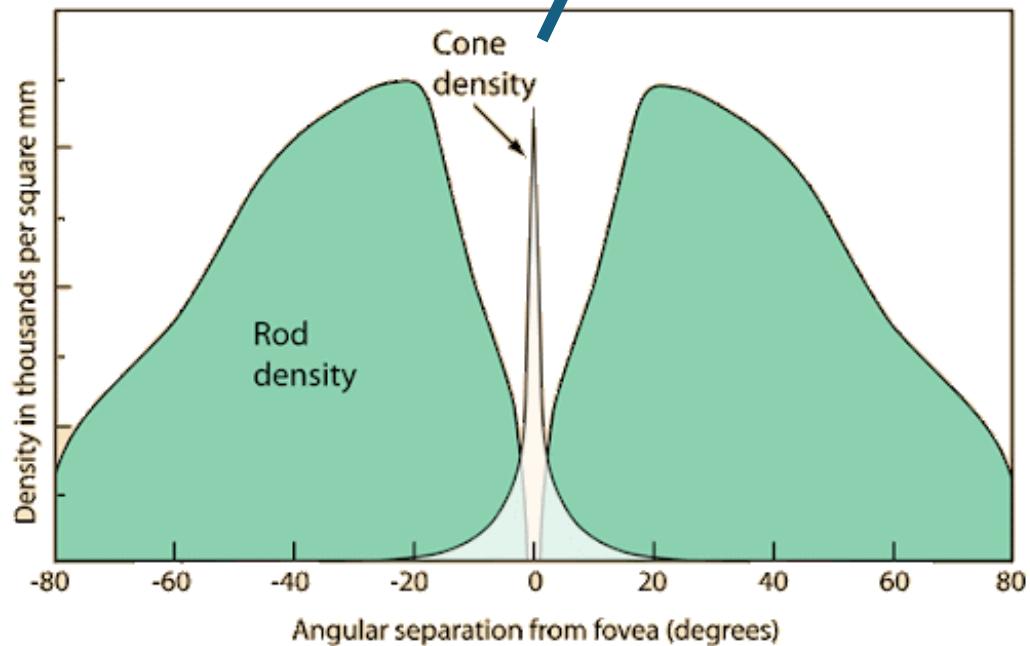

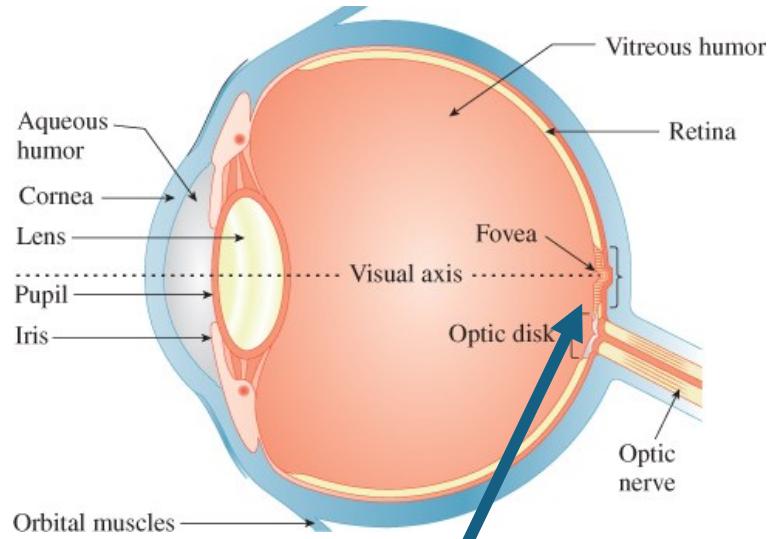

# The Retina

Filled with cells that respond to light

- Cones
- Rods

# Rods and Cones

**Cones are mostly concentrated at the fovea**

**Rods occupy the remaining areas**

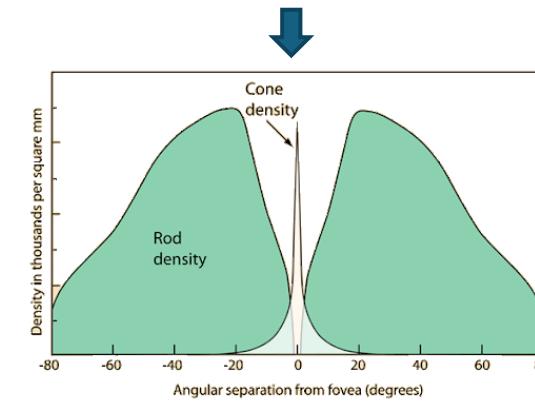

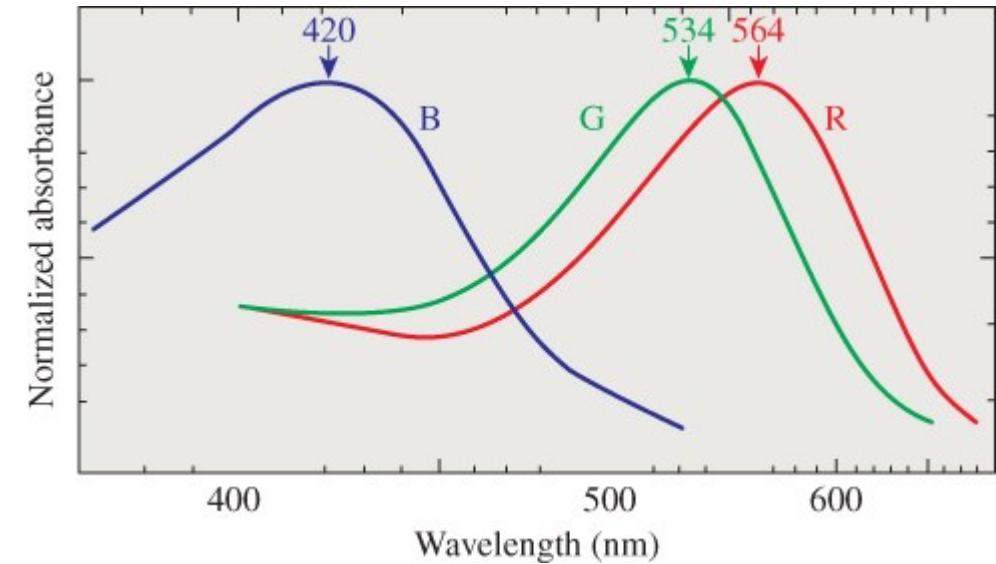

# Cone response

Three types of cones

- Short (B), Medium (G), and Long (R) wavelength detectors

Responsible for colour vision

Best at seeing details

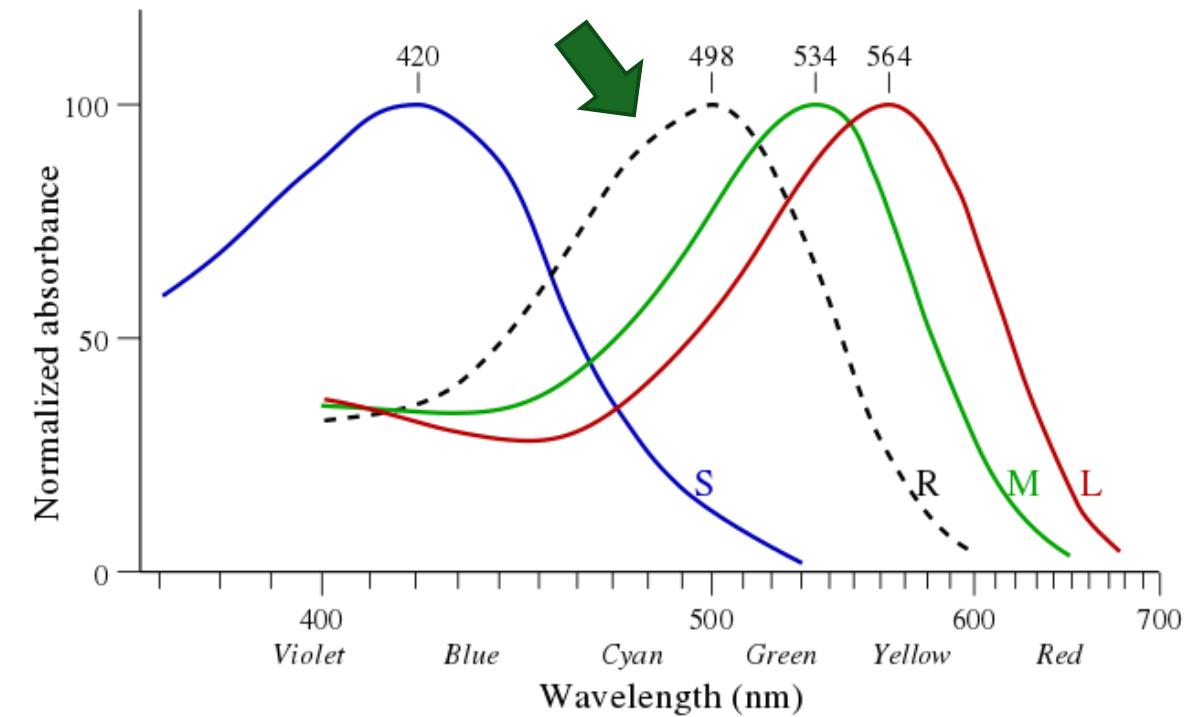

# Rod response

Slower to respond to light

- More sensitive to small amounts of light
- Vision in low-light conditions

Most sensitive to light around 498 nm (green-blue)

But they **do not provide** colour information

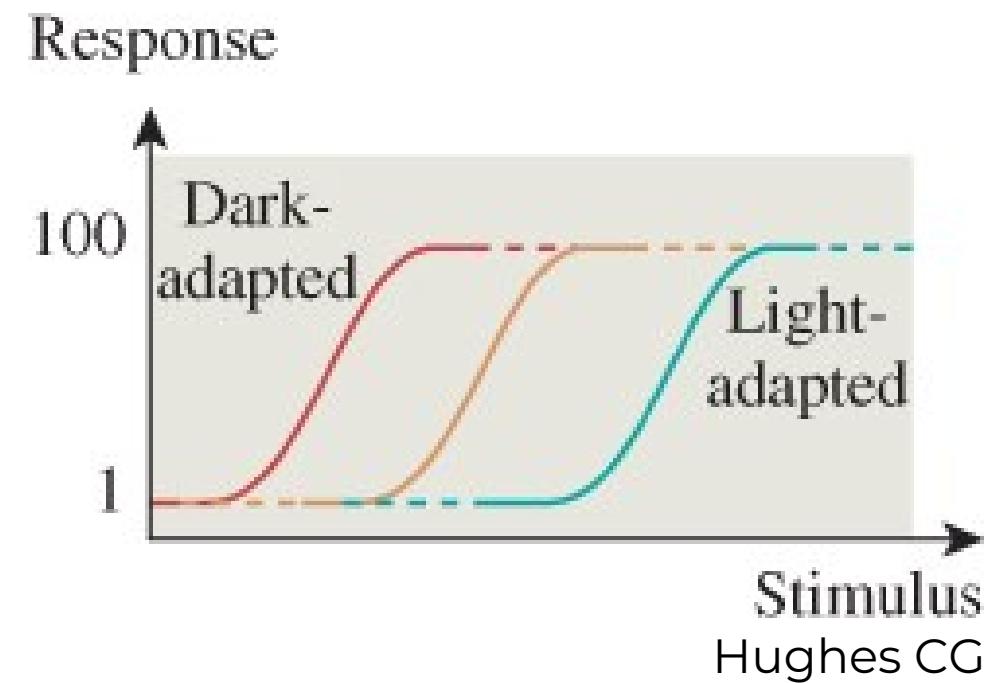

# Brightness and Dynamic Range

The eye has a limited dynamic range in a particular context, but...

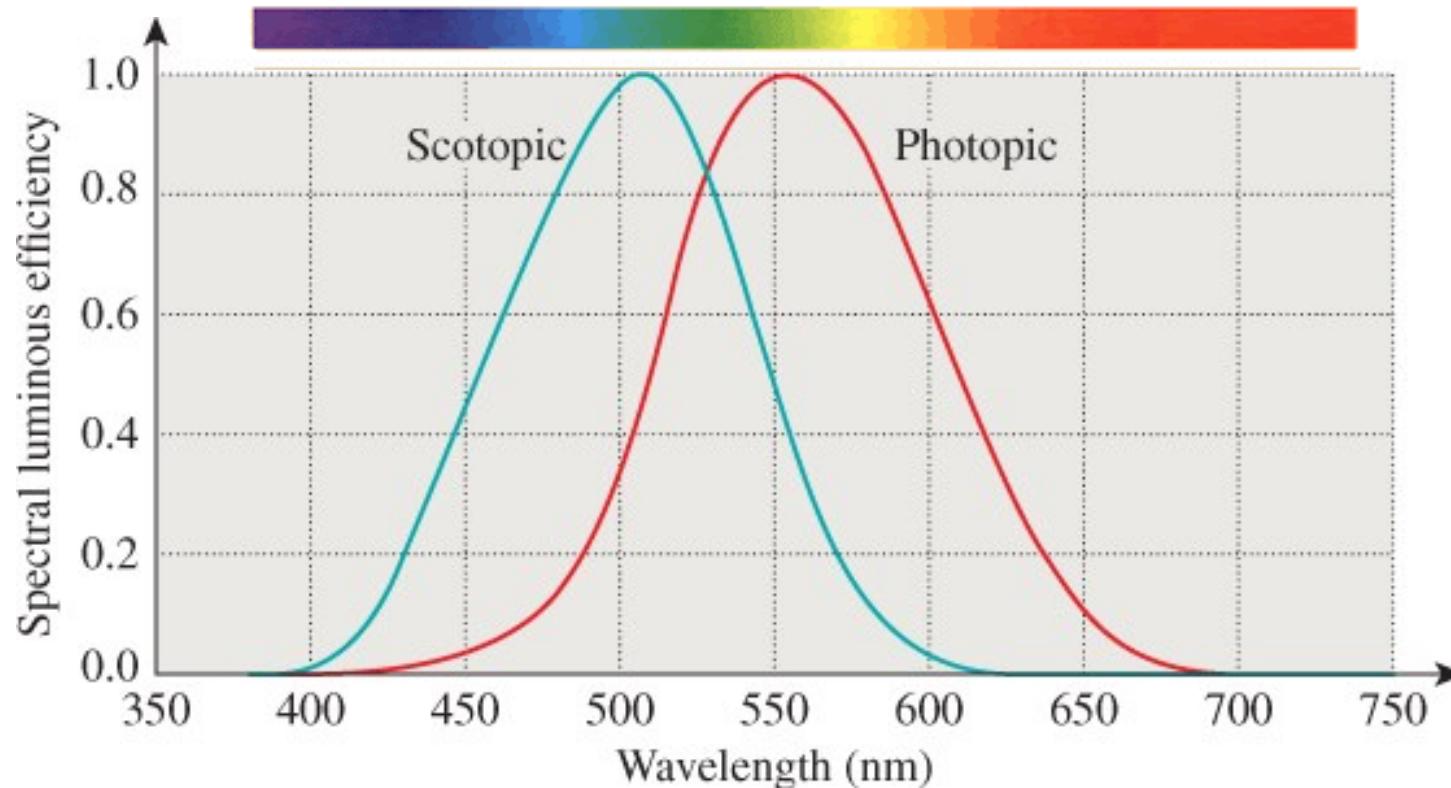

The eye adapts to the circumstances

- It allows handling the wide range of illumination in everyday life

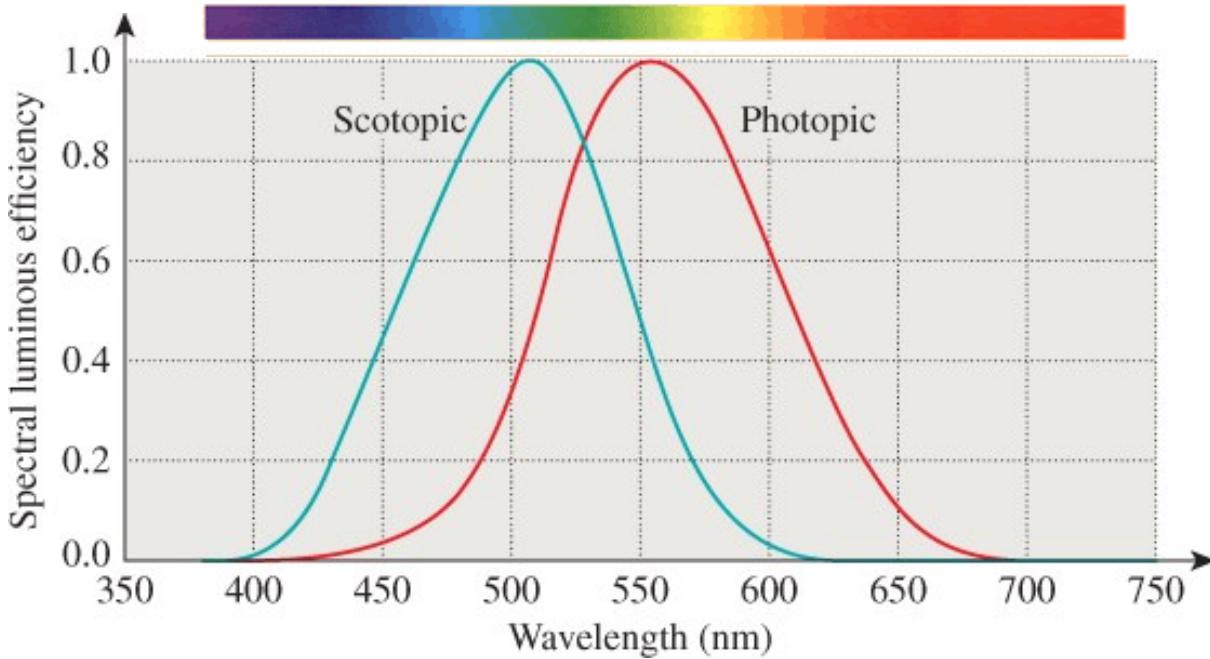

Cones and rods play complementary roles and adapt to the existing brightness levels

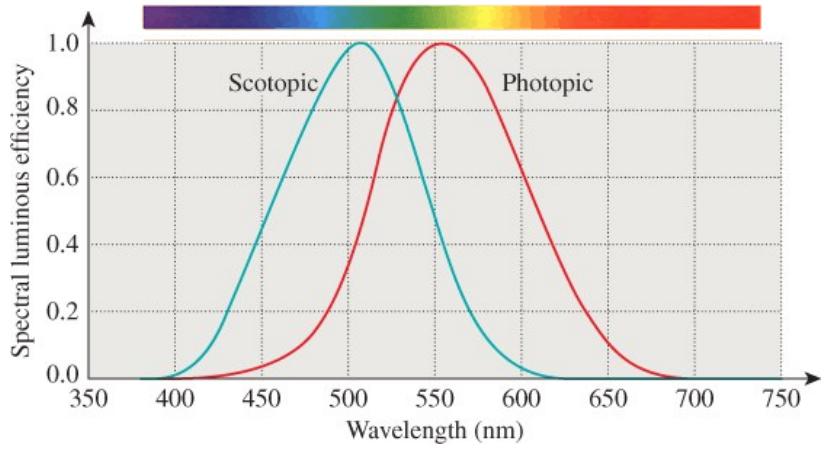

# Rods (scotopic) and cones (photopic) vision complementarity

# Explain...

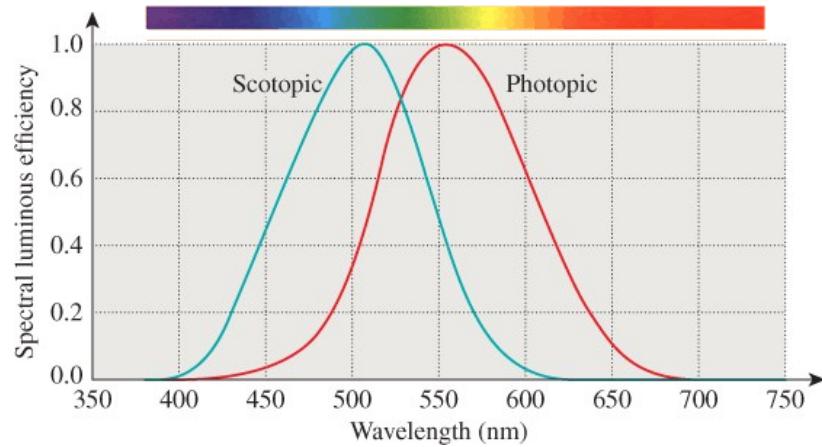

- Police vehicle lights
- Ambulance vehicle colours
- Lighting for astronomy and submarines

# Explain...

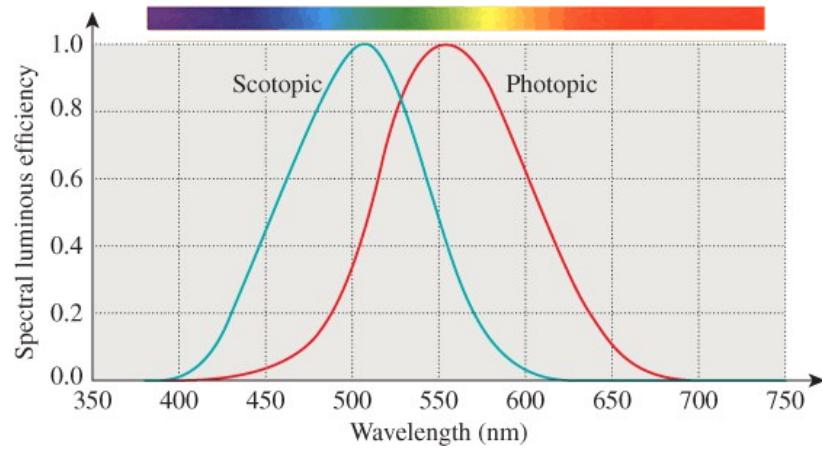

- Police vehicle lights

# Explain...

- Ambulance vehicle colours

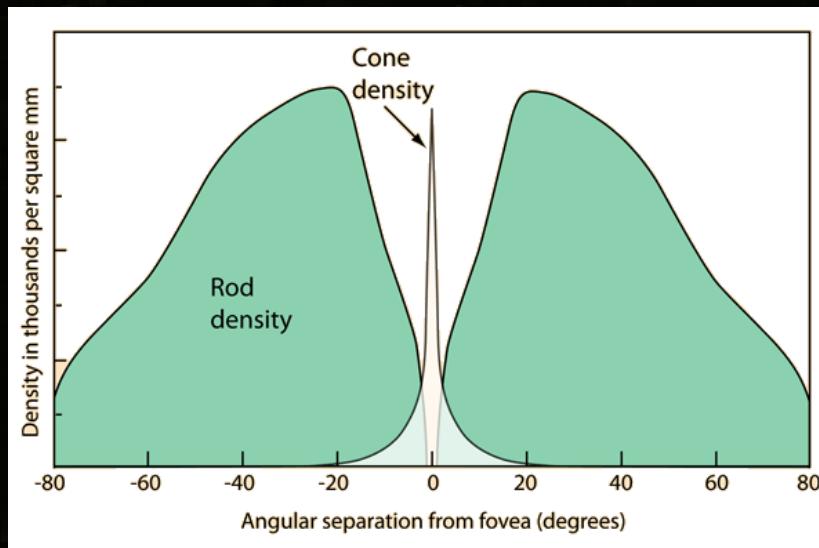

# Explain...

- Lighting for astronomy and submarines

With what you already know about visual perception,  
what is the best procedure to be able to see  
a very faint star in the night sky?

# Visual Sensitivity

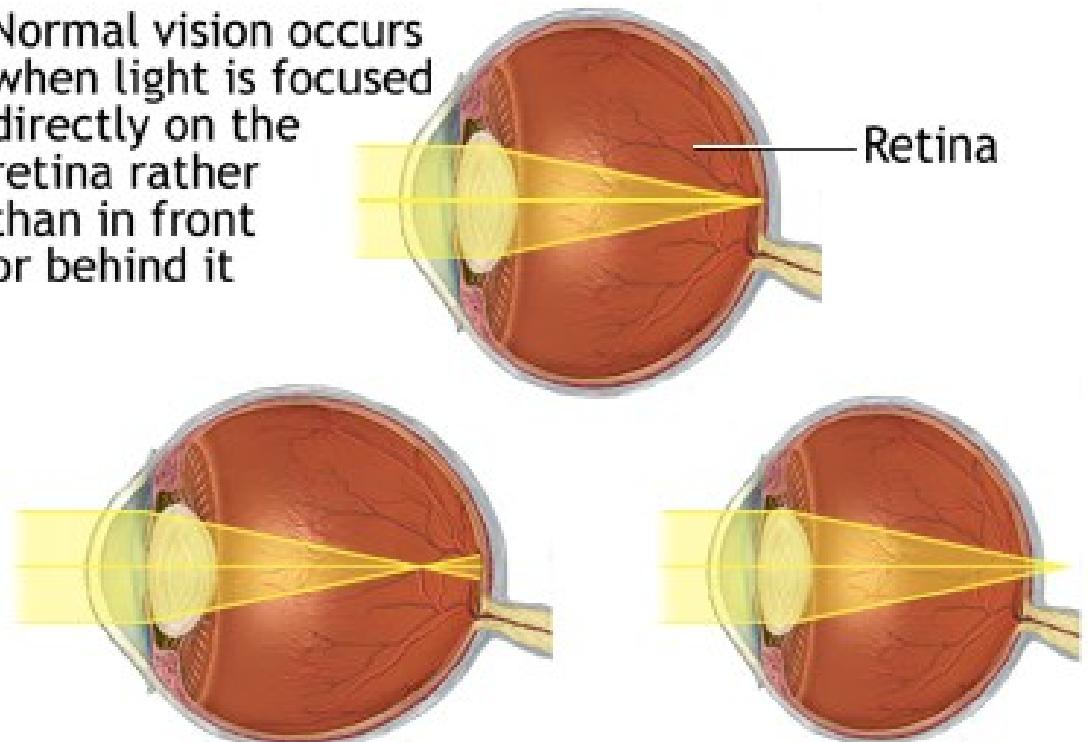

and some useful concepts

# Acuity is better at the fovea

Sam is getting old, what is happening to his eyes?

Normal vision occurs when light is focused directly on the retina rather than in front or behind it

Nearsightedness: visual image is focused in front of the retina

Farsightedness: visual image is focused behind the retina

 ADAM

# Visual Angle

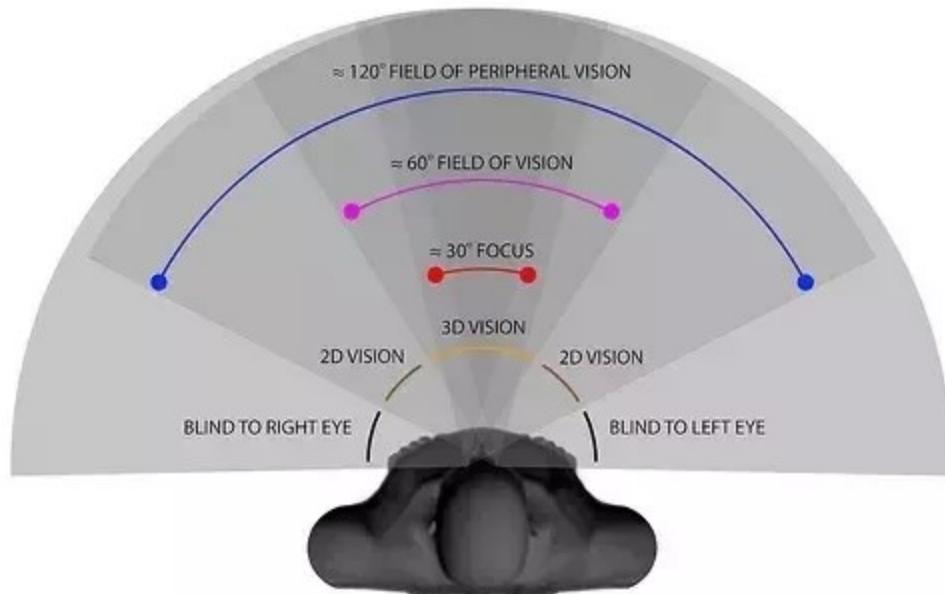

Is how wide an angle an object occupies in the eye

It depends on the distance and size of the object

It can be a measure for calibration of size among various displays

# Visual Angle

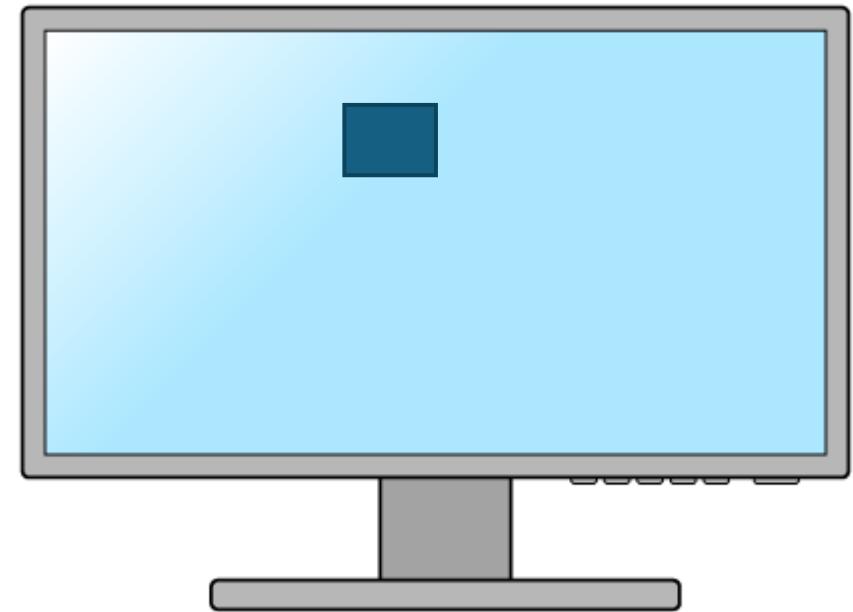

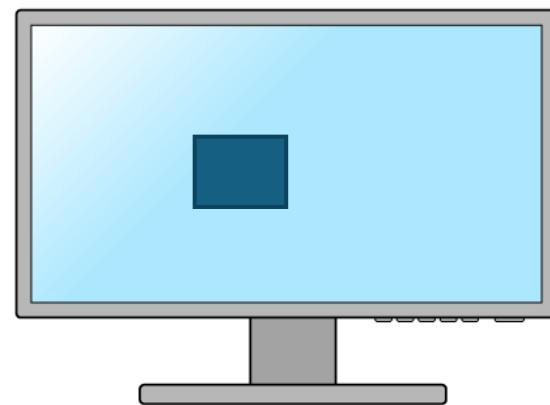

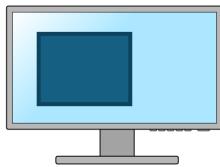

Important to control what the person sees and with what capabilities

Depends on the distance to the target

# Visual Angle

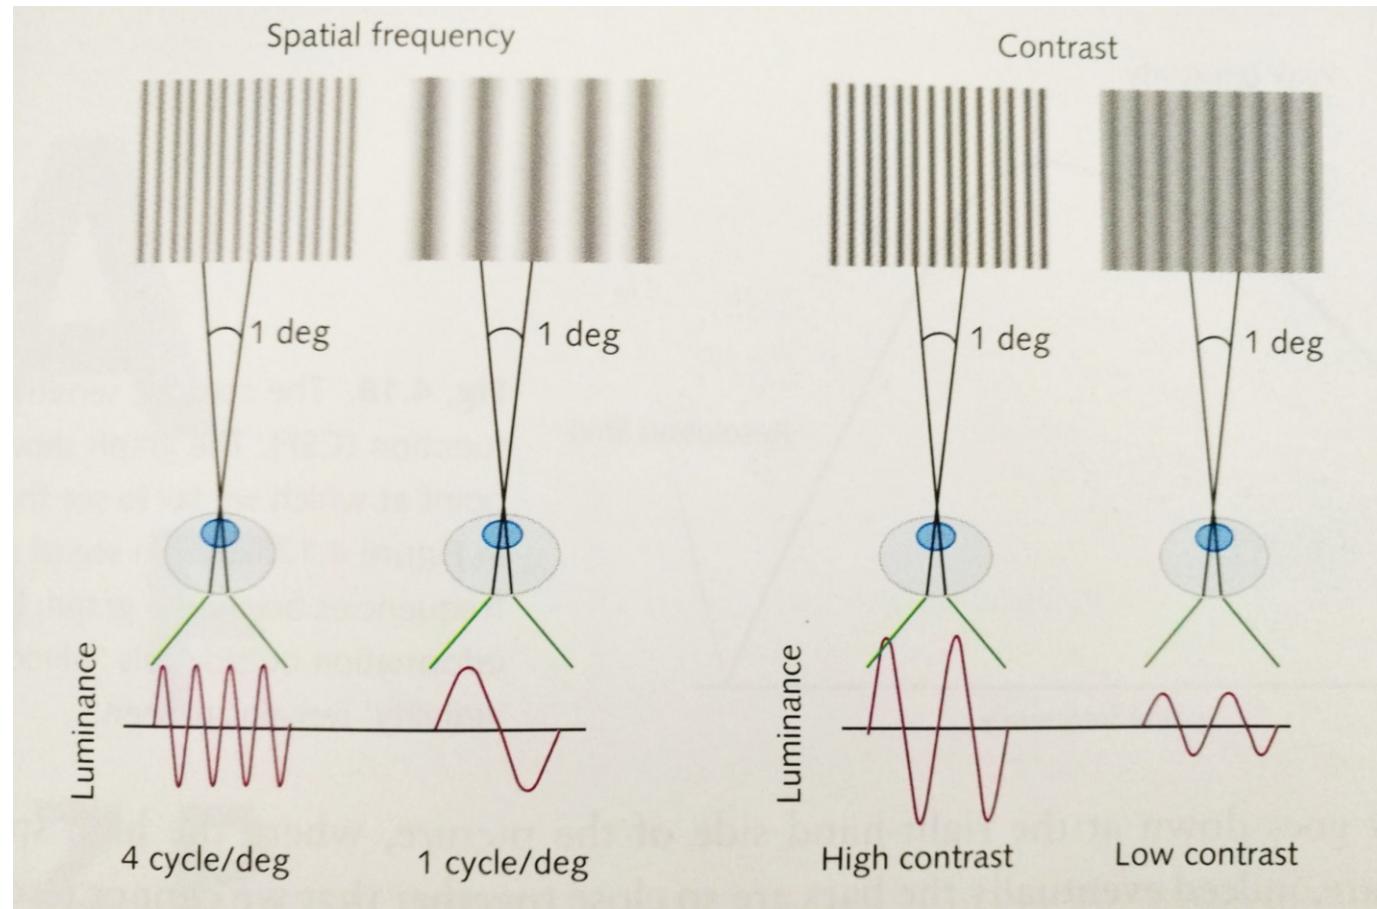

Ensure view size calibration

# Spatial Frequency

Many changes in a particular region correspond to a higher spatial frequency

**Low spatial frequencies** are like having **a pen that cannot change direction rapidly** (which would be high frequencies)

# Spatial Frequency

Low spatial frequency concerns overall aspect

**Broad SF**

**High SF**

**Low SF**

High spatial frequency concerns fine details

But WHY do I need to know this??  
**WHY?**

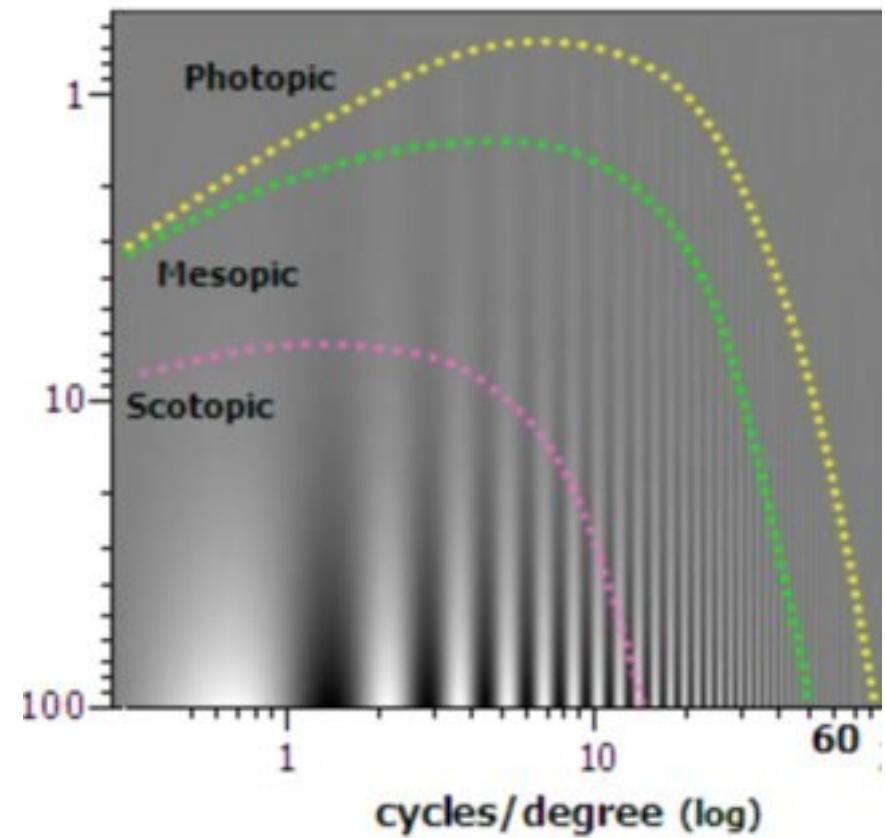

# Contrast Sensitivity

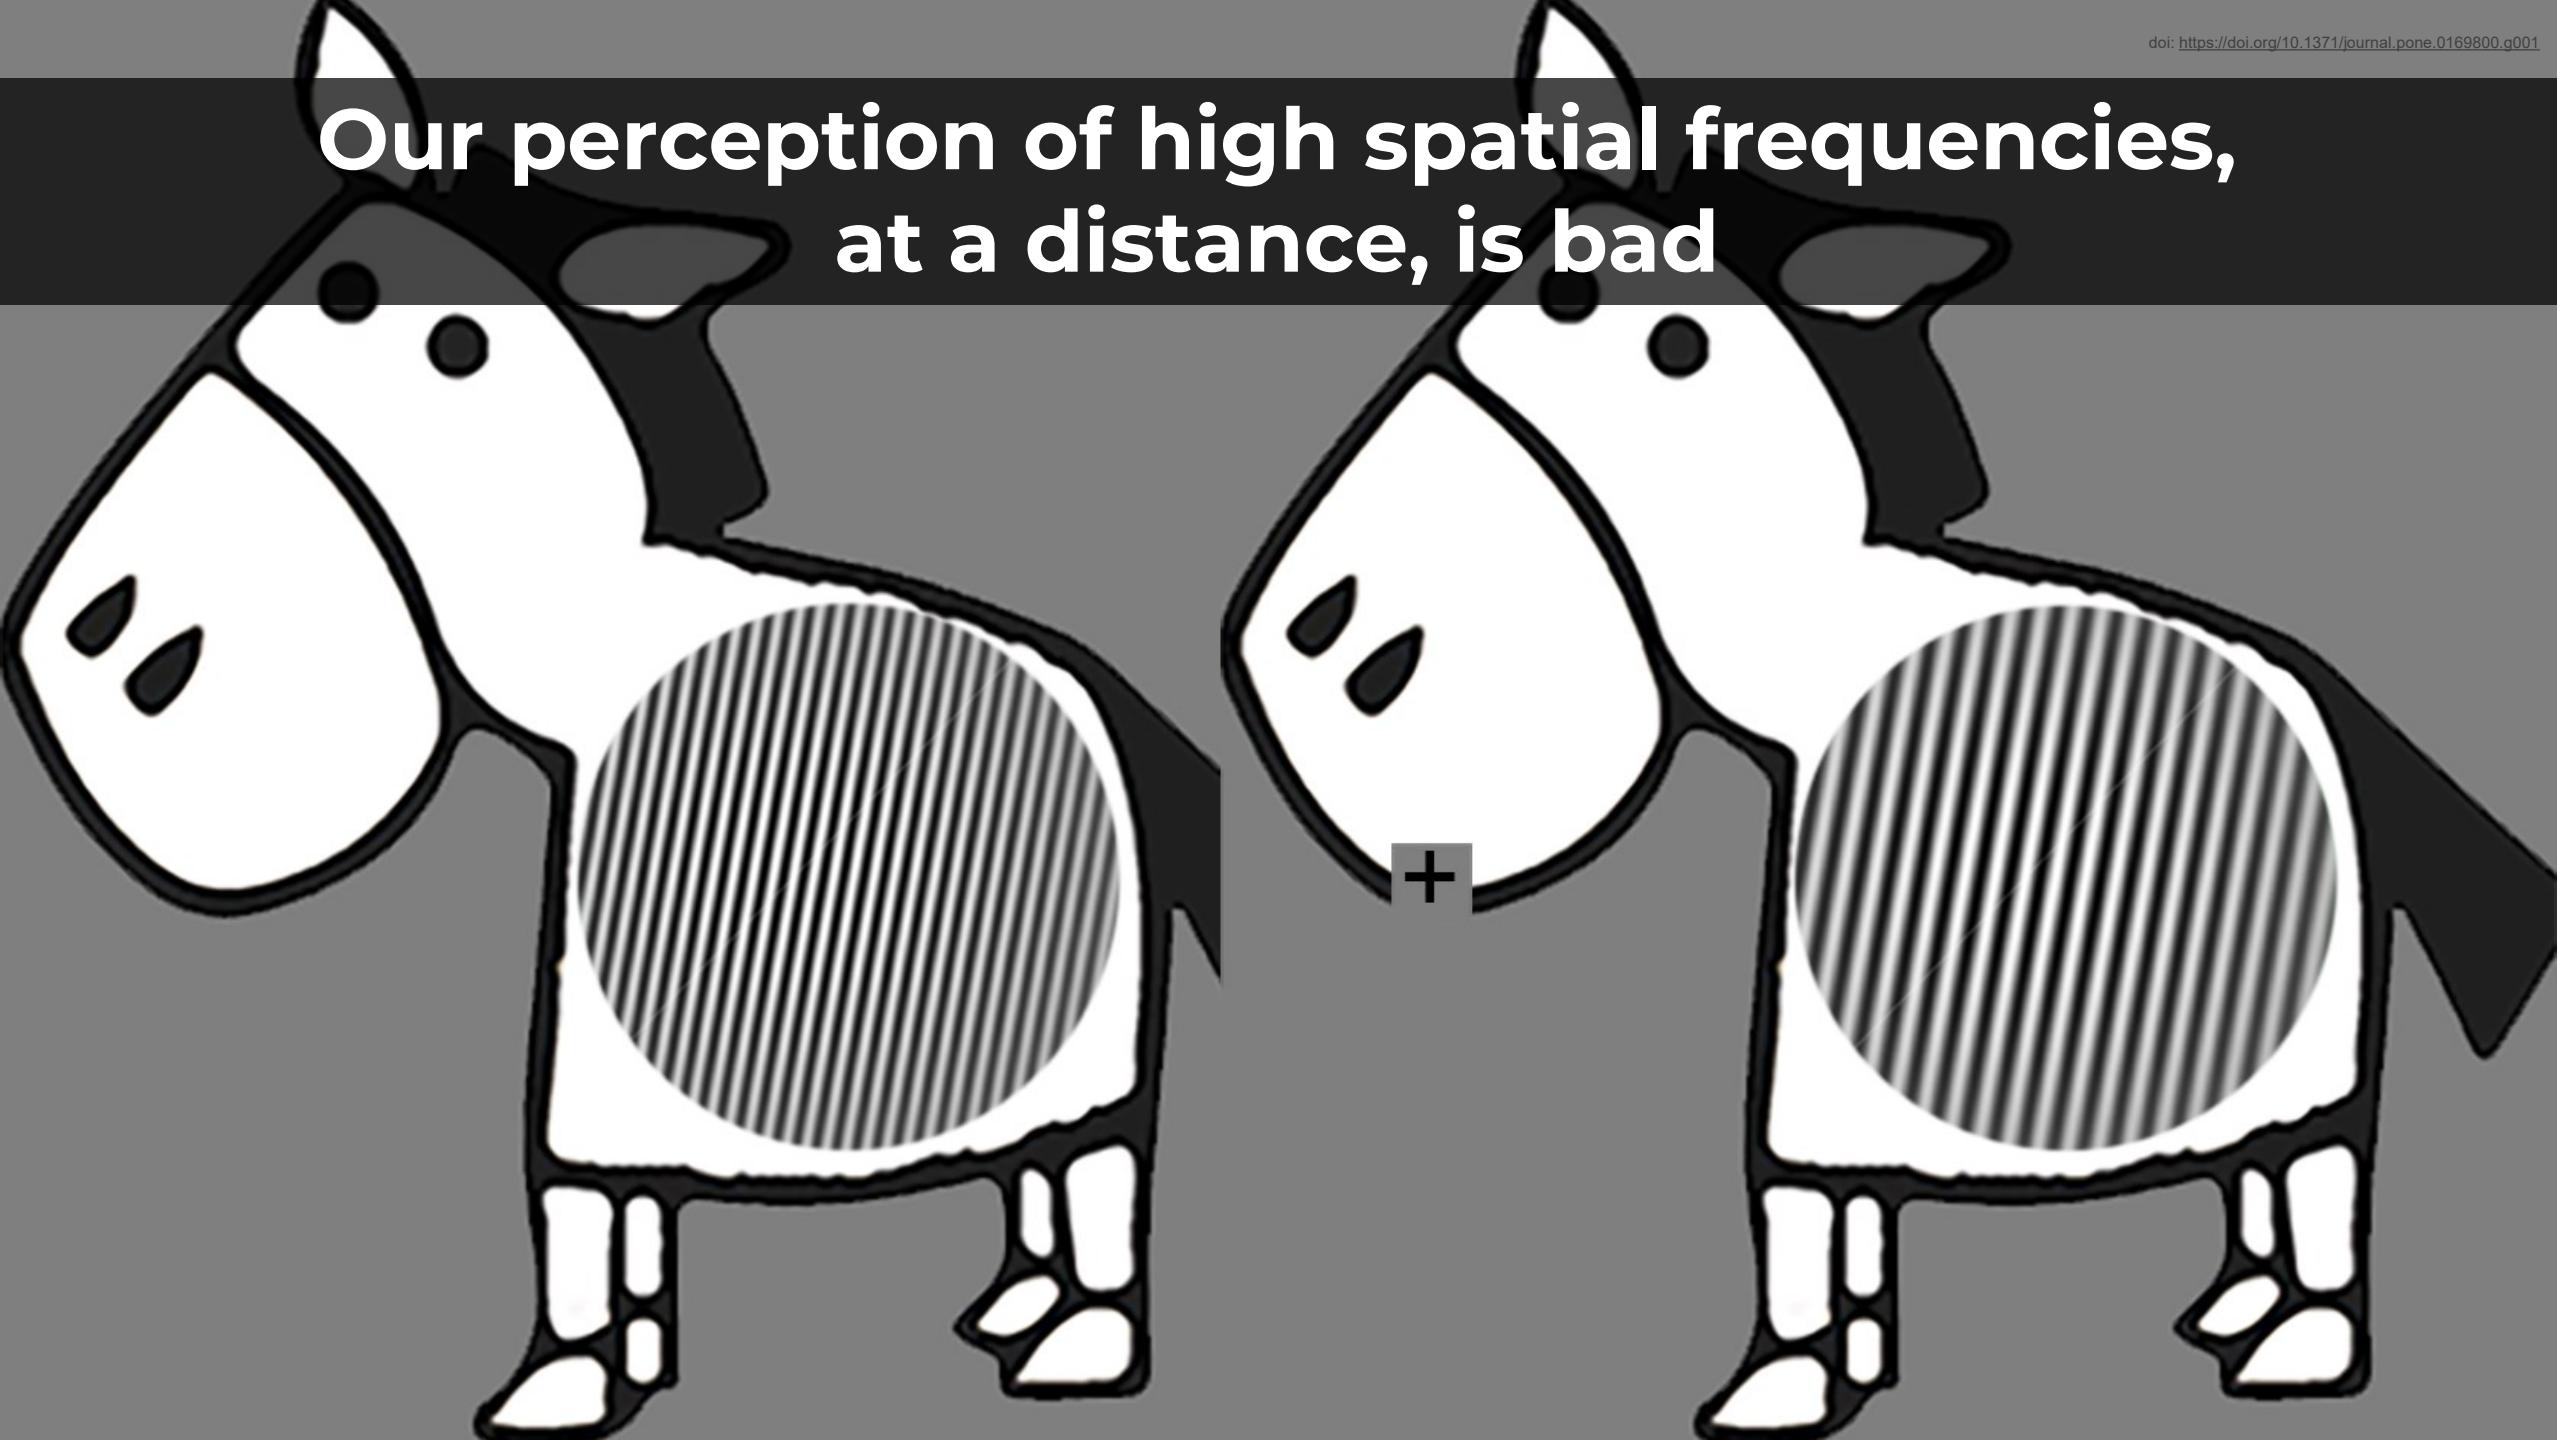

High detail in low contrast is not perceived

Scotopic (rods) vision has low resolution  
(remember best acuity is at the fovea)

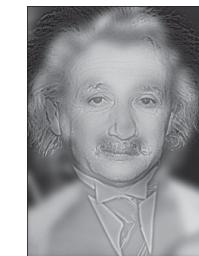

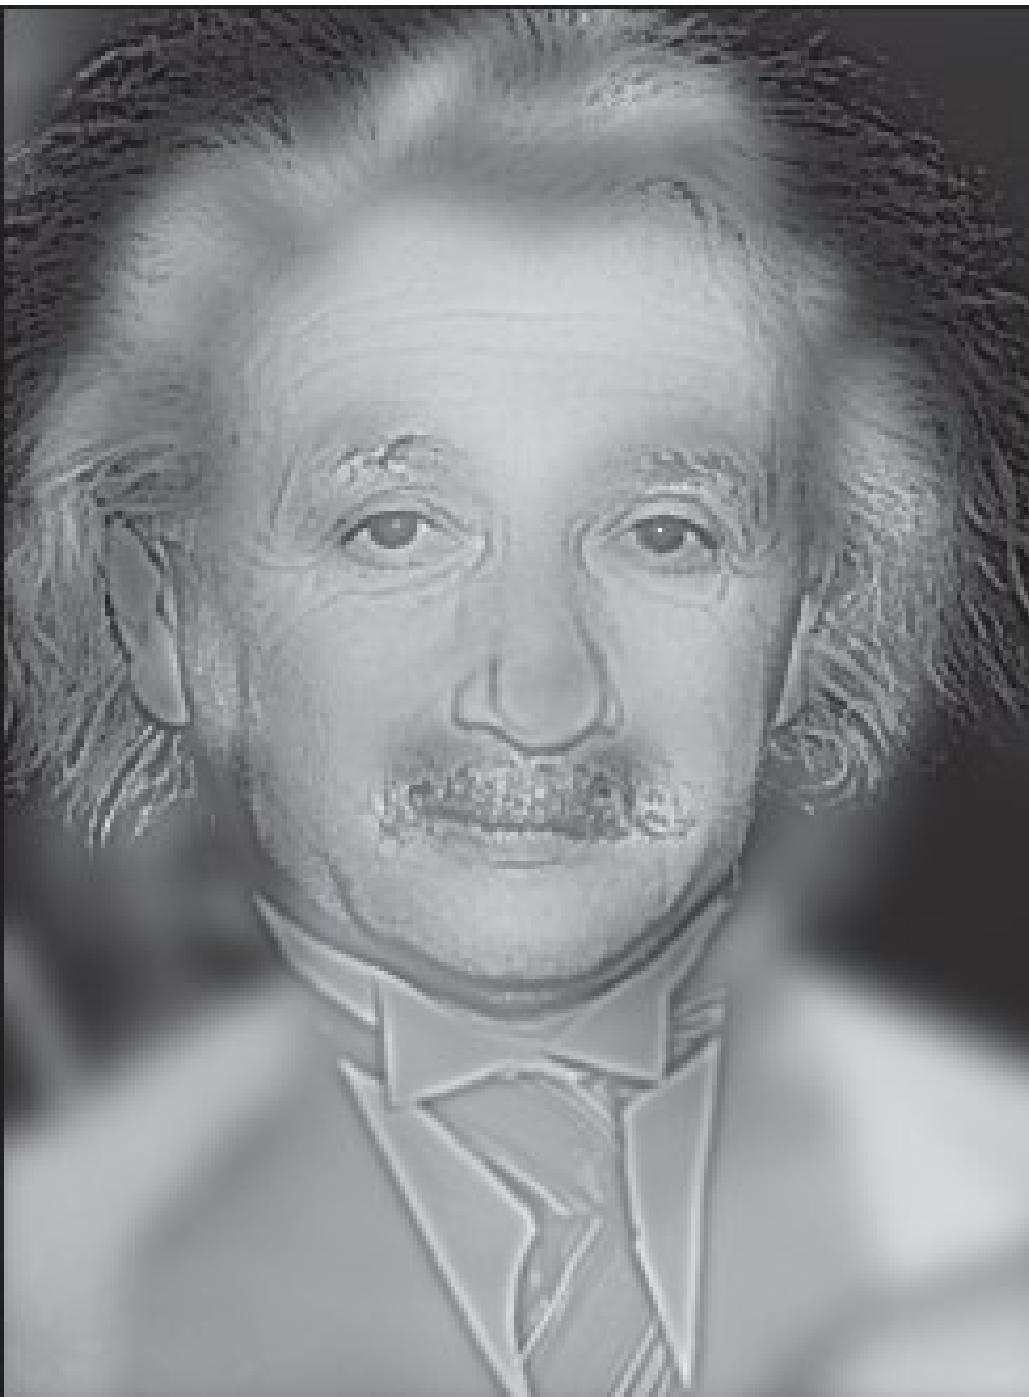

No need to spend too much resources rendering objects at the periphery of our vision

Our perception of high spatial frequencies,  
at a distance, is bad

- Different appearance when seen from close or afar
- **Can you explain why?**
- What does this tell us that is important for computer graphics?

No need to spend resources rendering far away elements in fine detail. We cannot perceive it!

A black and white photograph of a zebra standing in a grassy field. The zebra is facing left, showing its profile. Its body is covered in distinct black and white horizontal stripes. The background is a blurred green field.

Does not seem a  
good idea for  
camouflage...

The background of the image is a dense, black and white pattern of zebra stripes. The stripes are oriented vertically and horizontally, creating a complex, swirling, and somewhat abstract design that resembles a forest of zebras or a迷宮 (labyrinth).

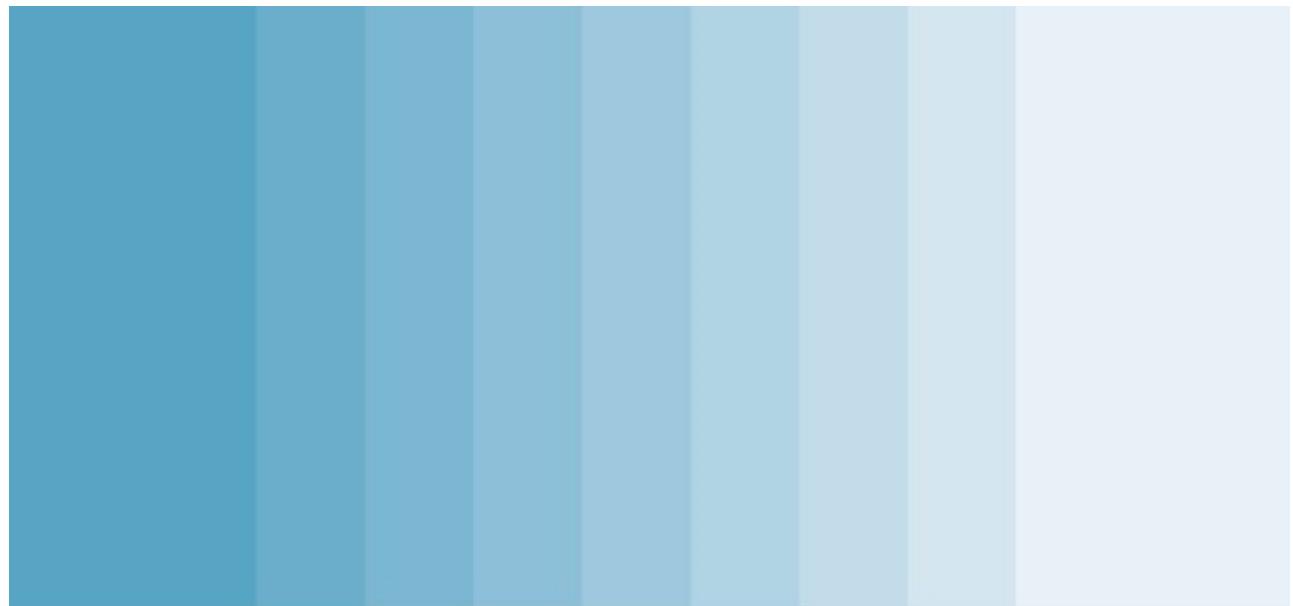

**Now imagine you want  
to choose a zebra to  
attack while looking  
from behind the bush**

# Mach banding

Each strip is a single colour, but...

It looks brighter on the left and darker on the right

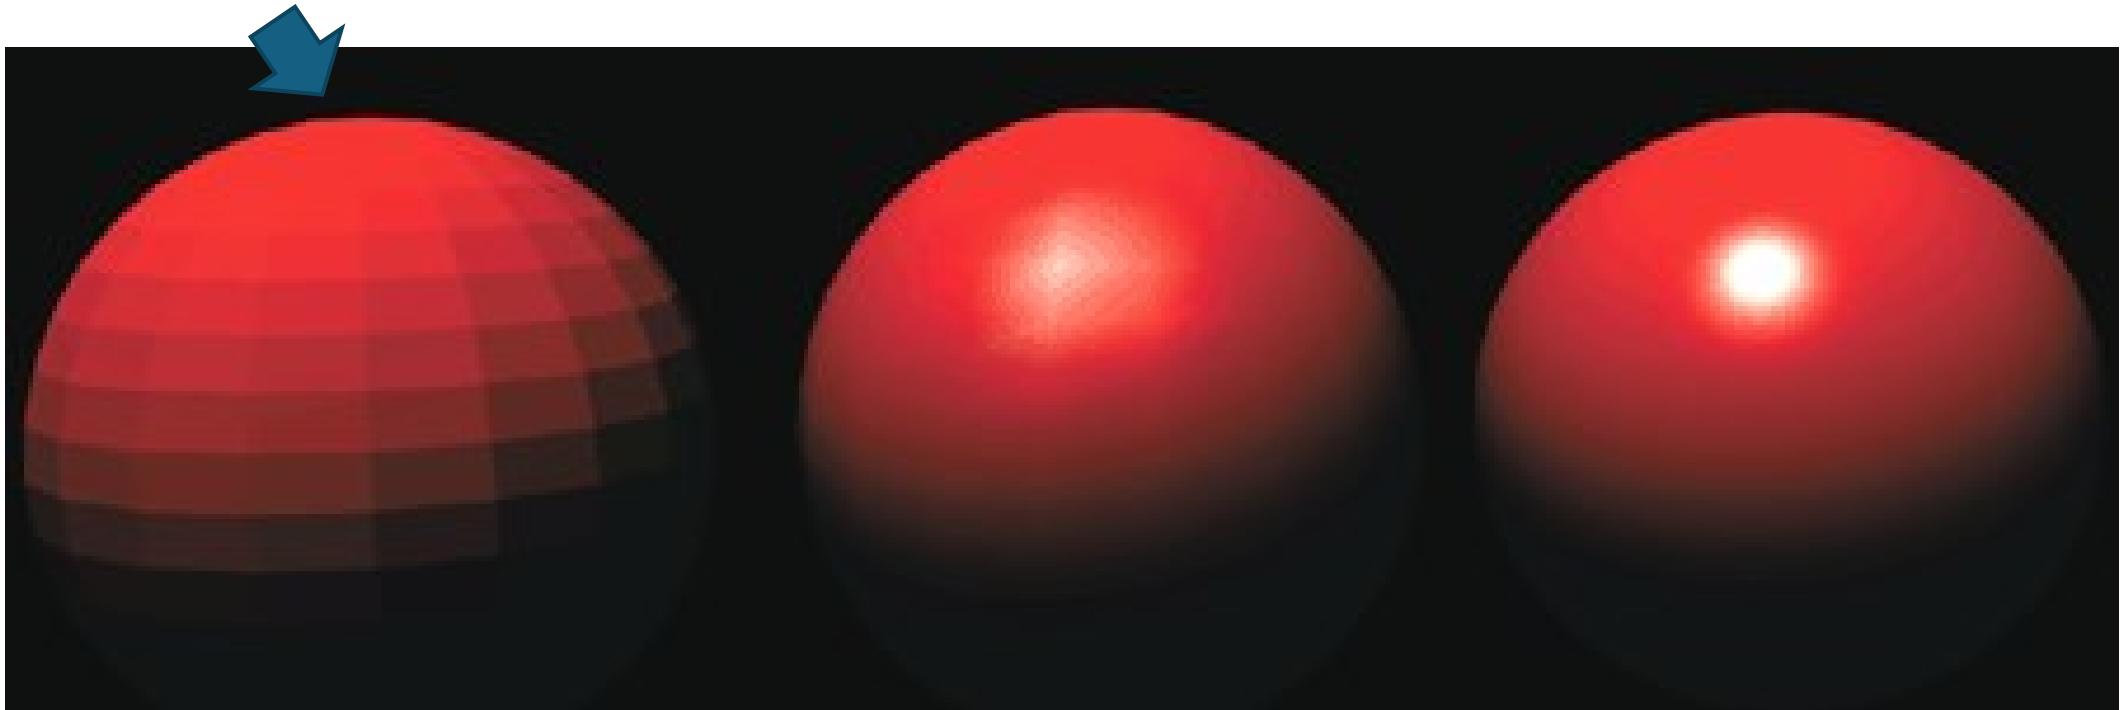

This strongly accentuates the perception of the transition between strips

Hughes, Fig. 1.13

# Mach banding

This explains why very simple illumination models provide such awkward results

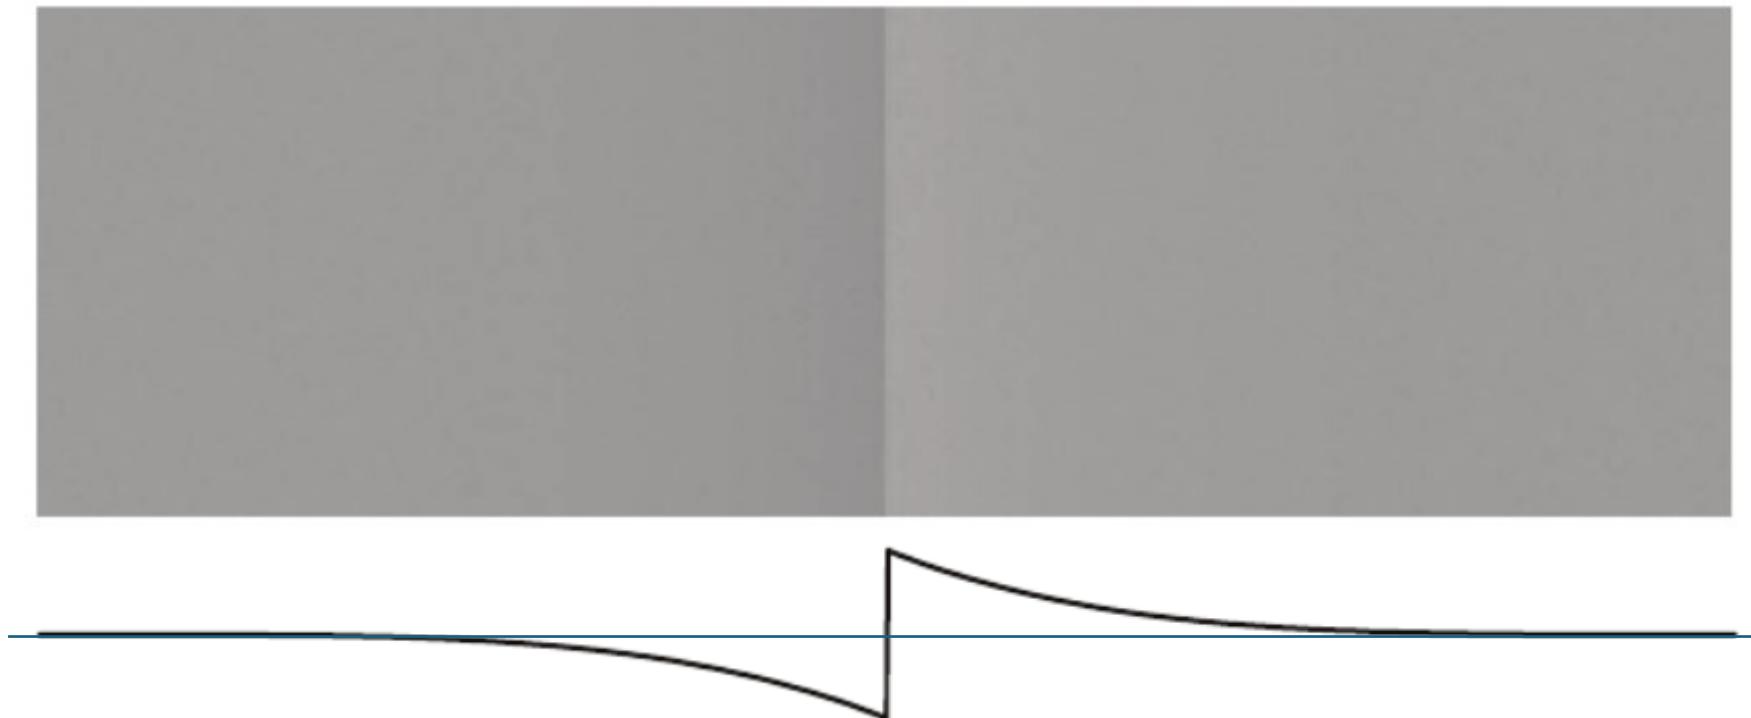

# Craik-O'Brien-Cornsweet illusion

It is rather easy to detect the brightest side

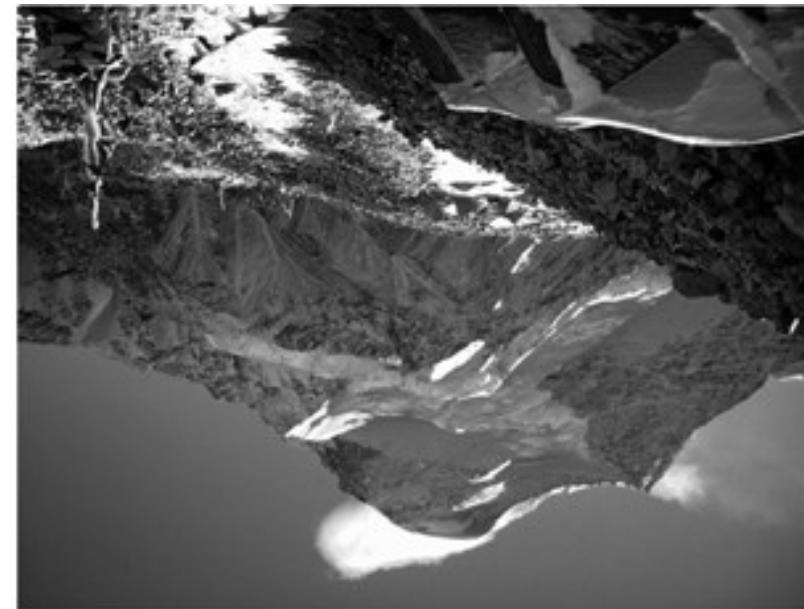

# Craik-O'Brien-Cornsweet illusion

The two halves are actually the same colour, with a glitch at the middle

# Object Recognition and its Complexities

Some scenes are easier than others.  
What's on the left? And on the right?

# Object Recognition and its Complexities

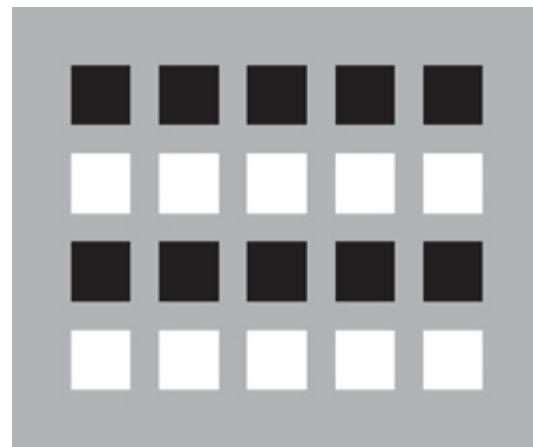

Orientation matters: when we make sense of it, it gets easier to interpret

# Gestalt Principles

# Object Recognition – Grouping

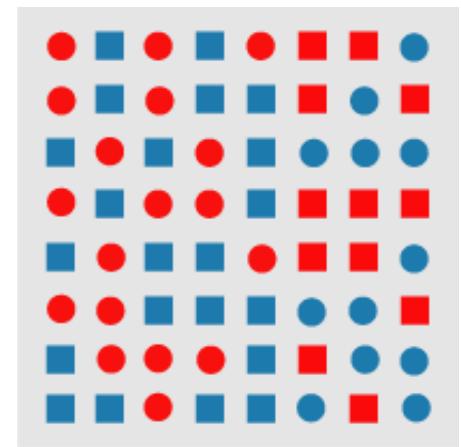

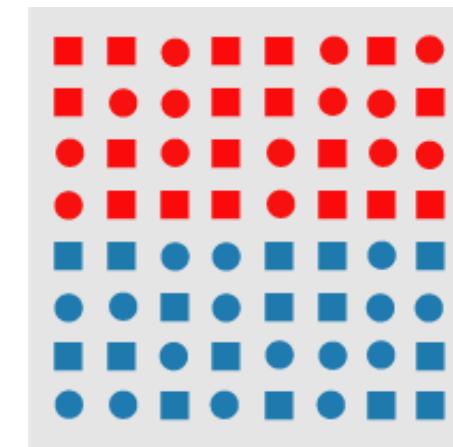

The first step is visual field organization into groupings

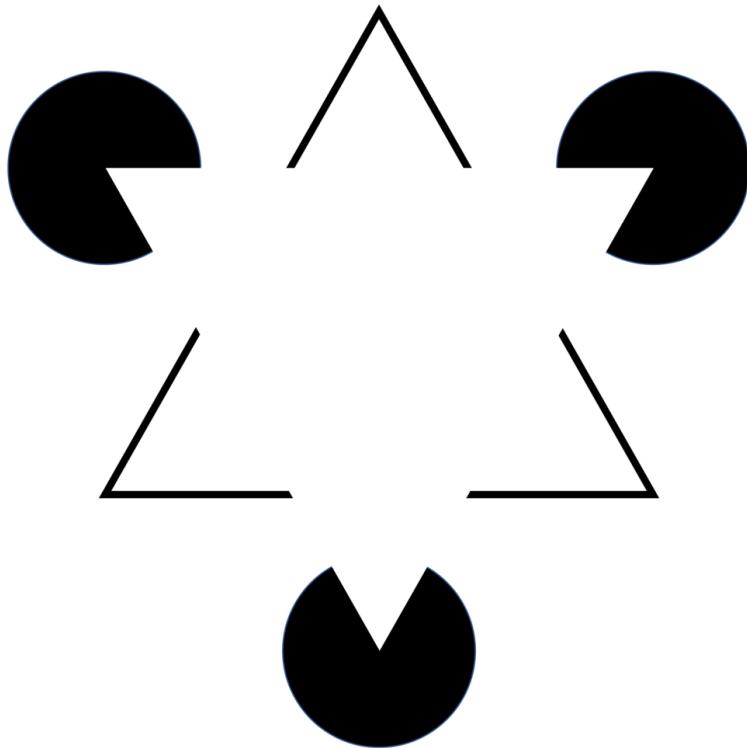

(a)

(b)

# Closure

# Continuity

# Figure/Ground

[https://www.toptal.com/designers/ui/gestalt-principles-of-design#:~:text=Our%20brains%20are%20built%20to,order%20\(also%20called%20prox%C3%A4gnanz\).](https://www.toptal.com/designers/ui/gestalt-principles-of-design#:~:text=Our%20brains%20are%20built%20to,order%20(also%20called%20prox%C3%A4gnanz).)

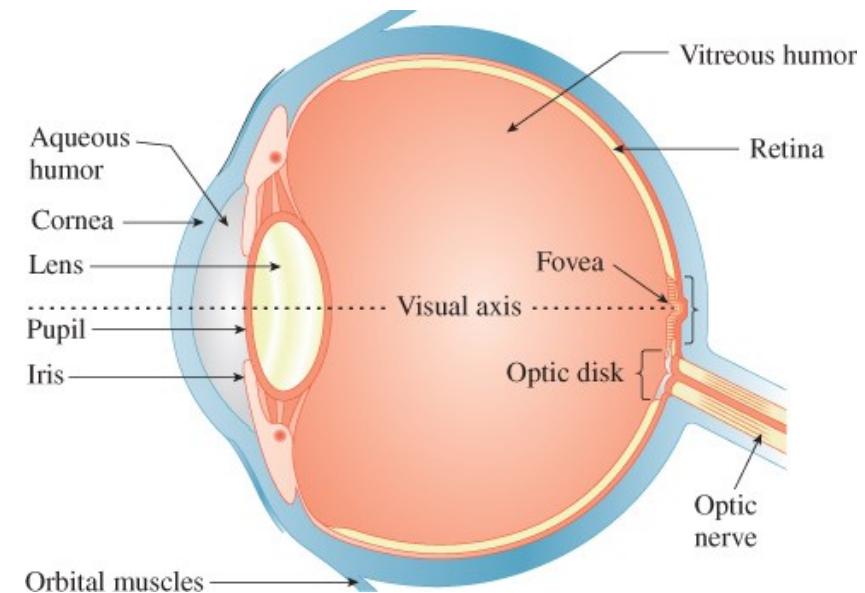

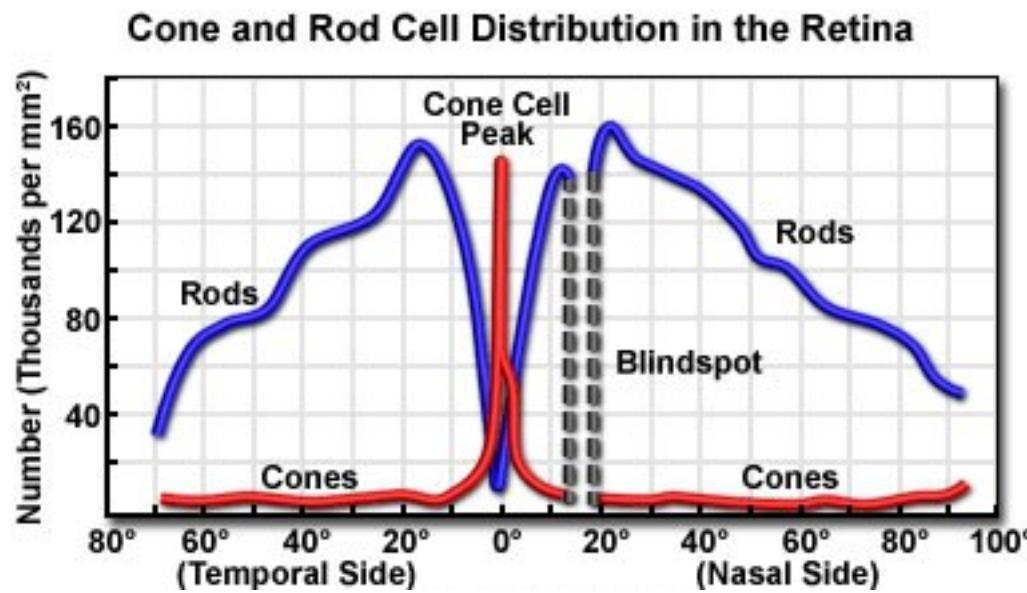

# Thumbs up

The disappearing finger...

# What is happening?

It is the eyes' blind spot!

# Colour Perception

We already talked about how the cones capture light in different ranges of colour

The visual system adapts to what is seen also based on the characteristics of the environment

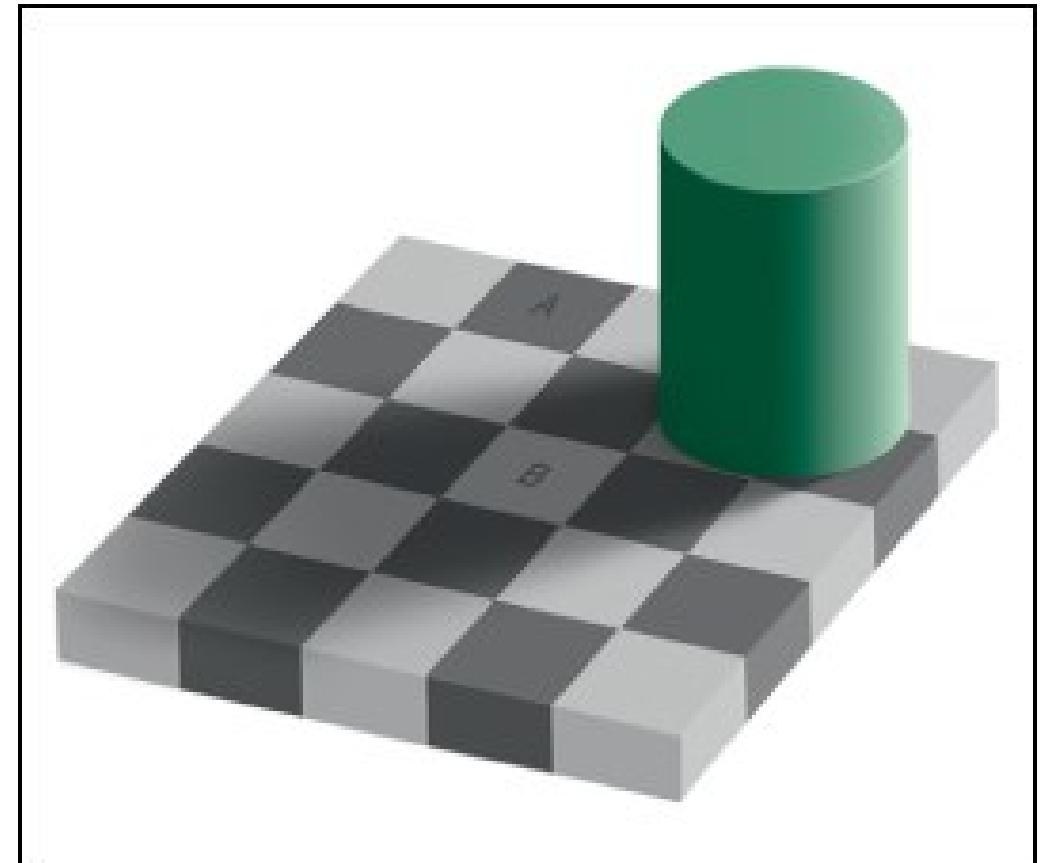

What we see in a photograph may not be what the person present at the scene actually saw

- We are in a different environment, hence, our visual system reacts differently

# Maintaining the sense of colour in challenging illumination

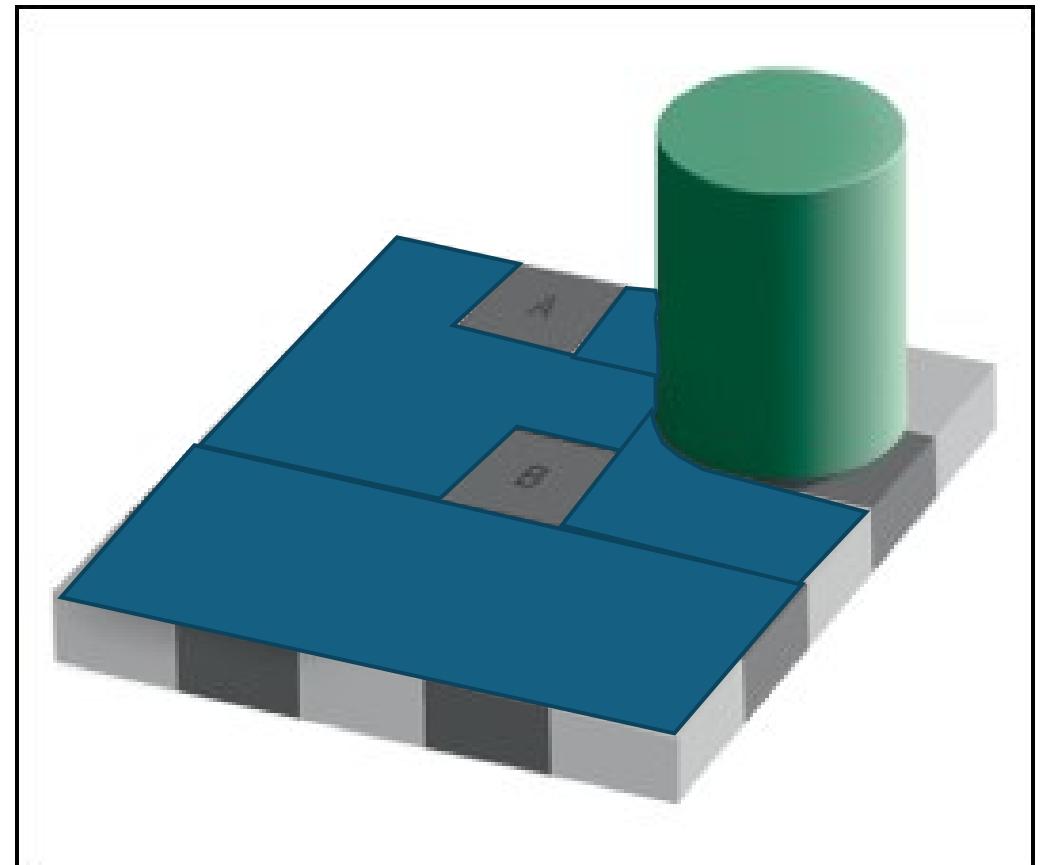

Despite the lighting differences over the board we can still distinguish which one is a lighter grey. A or B?

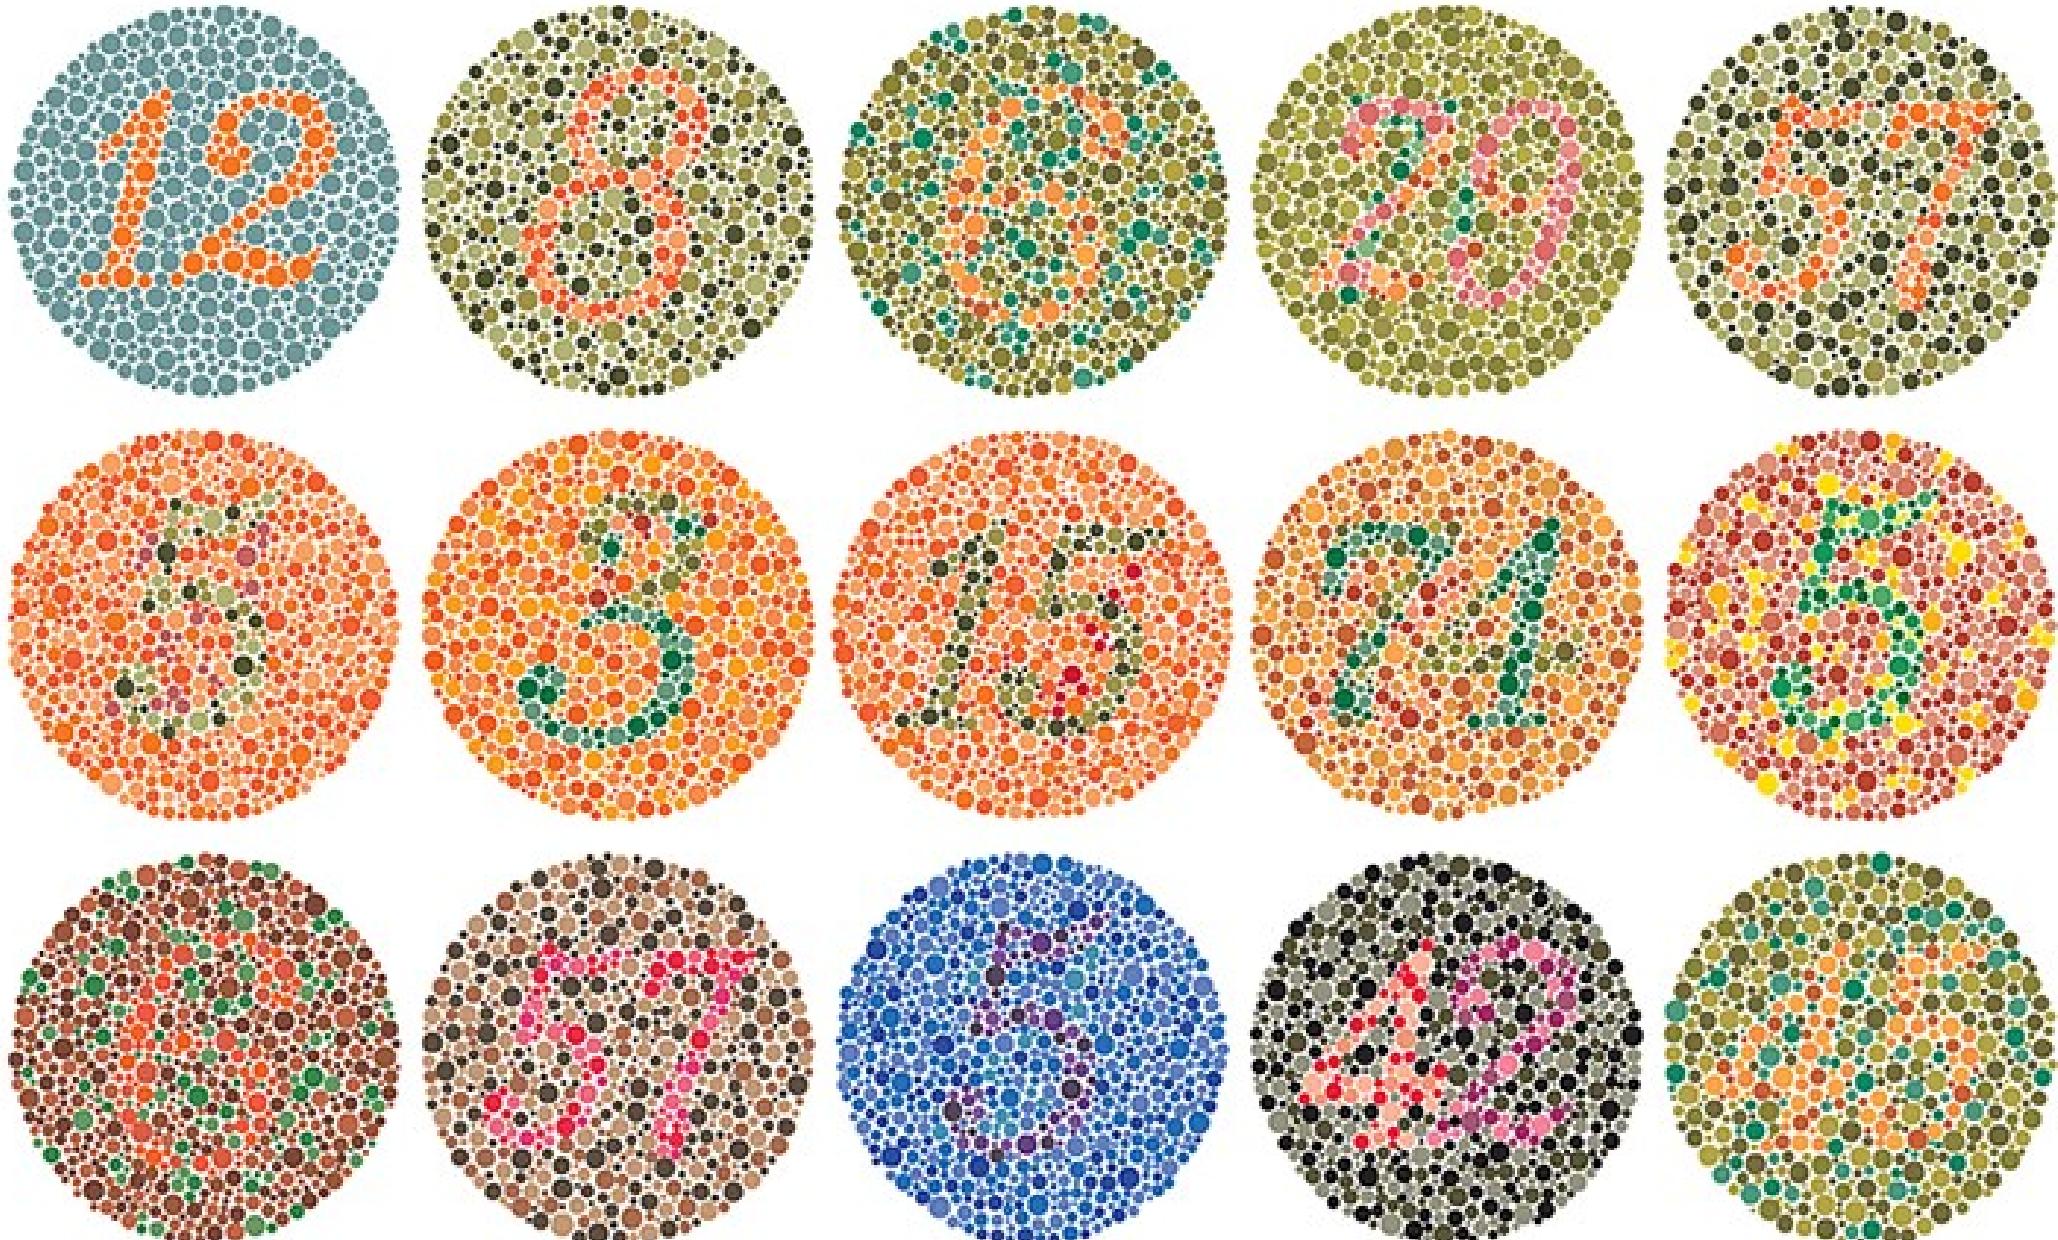

Colour constancy

# Colour Constancy

They are actually the same colour

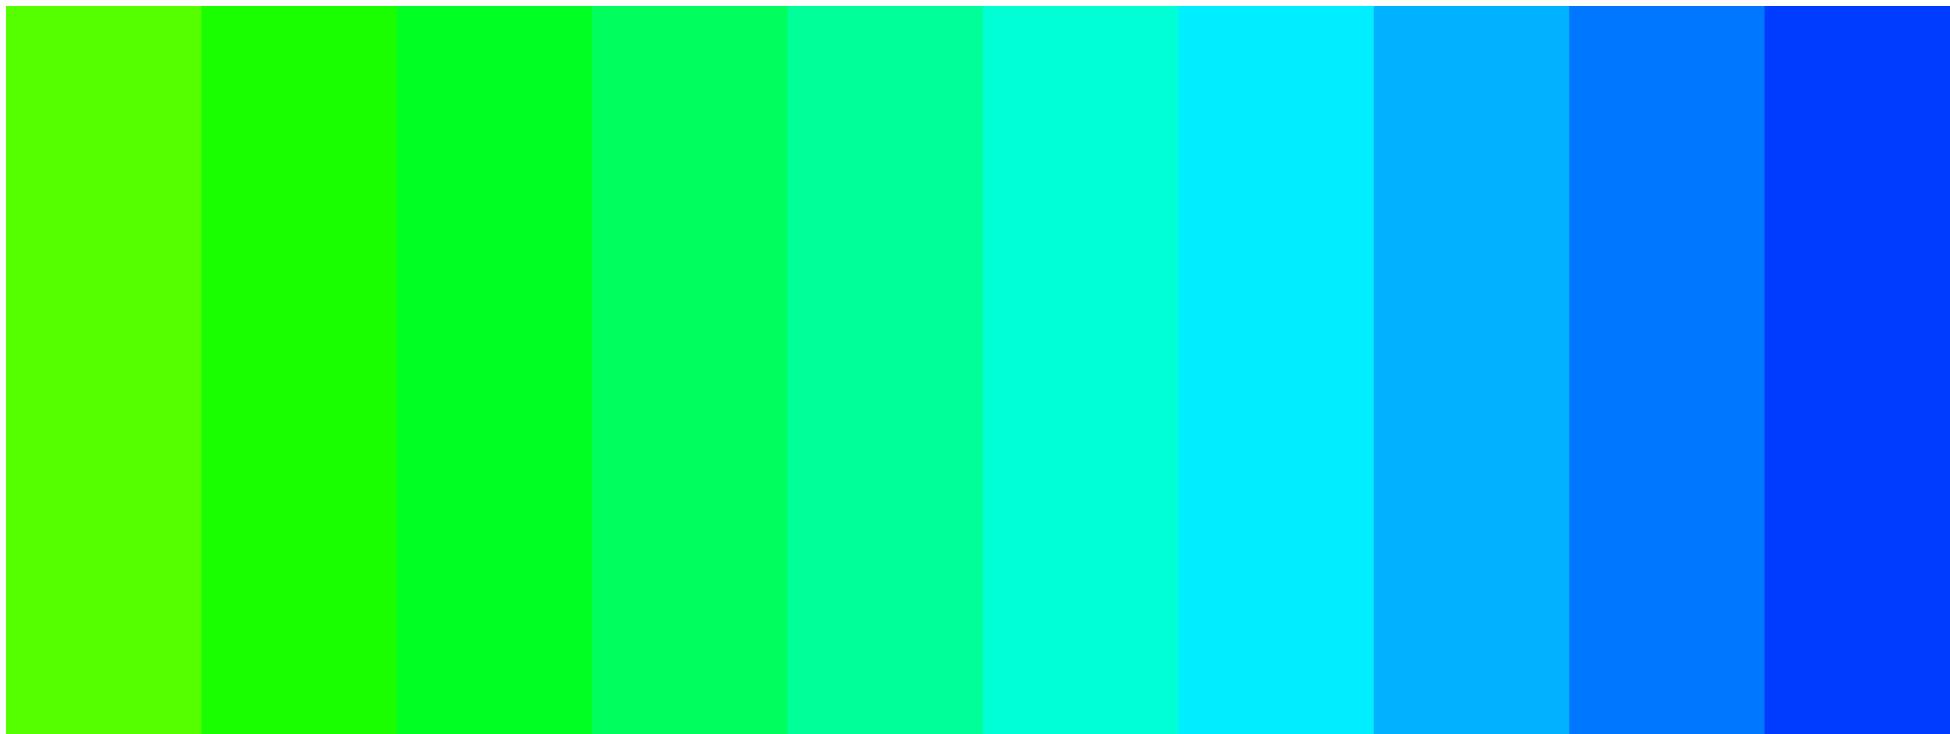

American Optometric Association

# Color Spaces – VERY small note

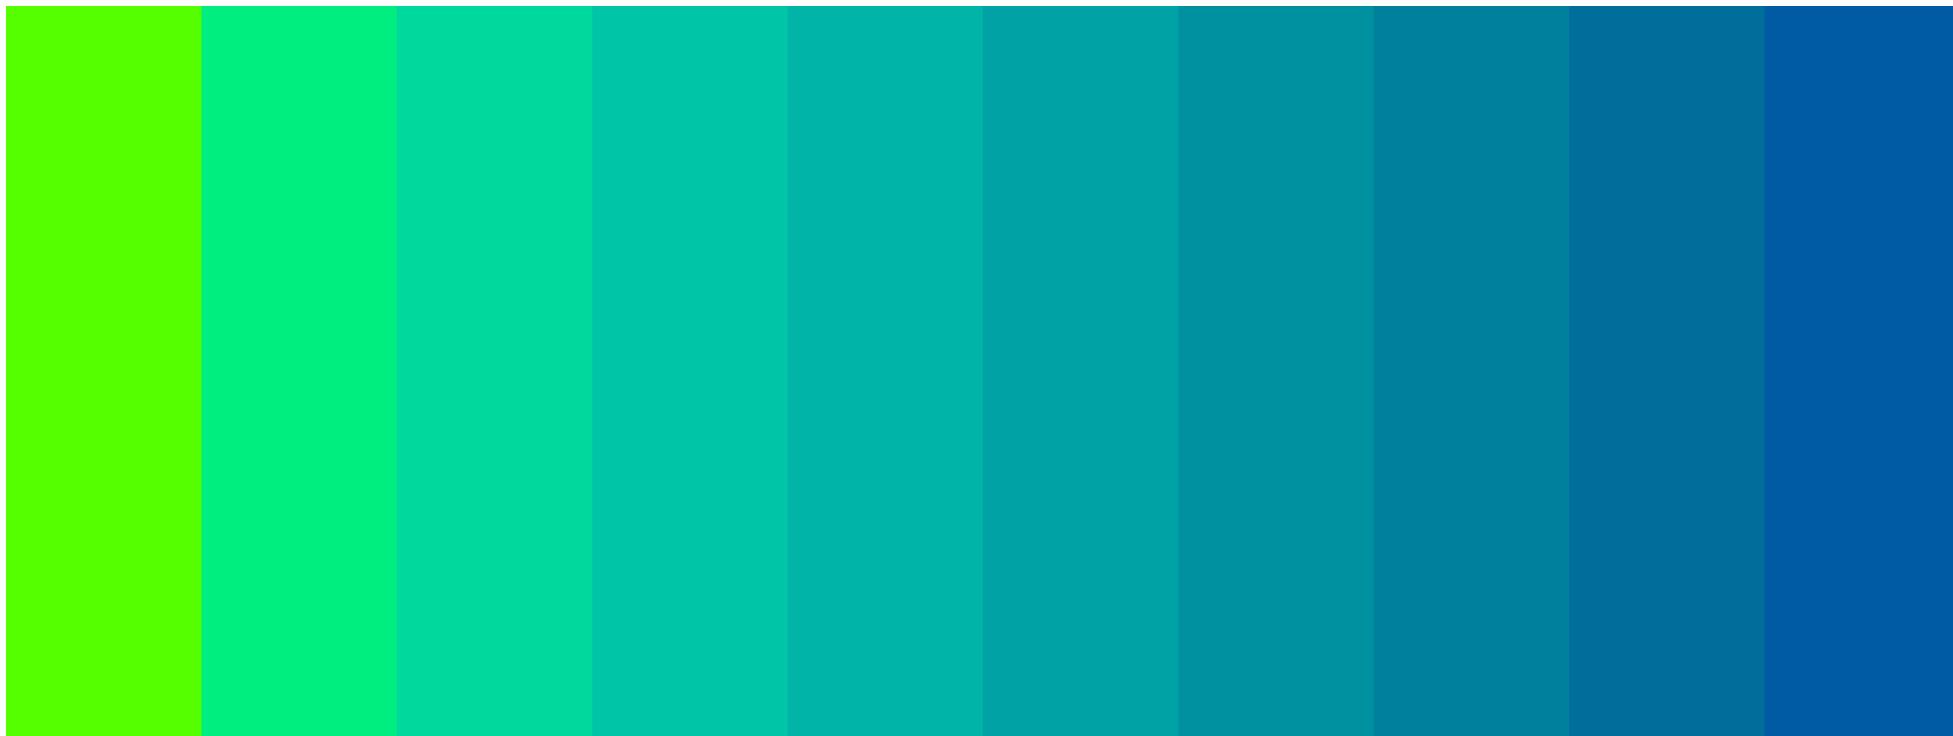

If we consider the common RGB representation, we cannot ensure perceptual distances (what is that?)

# Colour Spaces – VERY small note

Perceptual colour spaces

- The distance between colours has a correspondence to perceptual distance
- E.g., CIE L\*u\*v\*

# Depth Perception

Monocular Cues

# Relative Size

More distant objects look smaller

# Texture Gradient

# Occlusion (interposition)

A landscape photograph of a paved road stretching into the distance under a dramatic sky at sunset or sunrise. The sky is filled with warm orange and yellow hues, with dark clouds on the right side. The road has a double yellow line and is flanked by green grass and a simple fence on the left. The perspective of the road lines creates a sense of depth.

# Linear Perspective

# Perspective

We immediately sense that something is inconsistent

Fundamentals of computer graphics

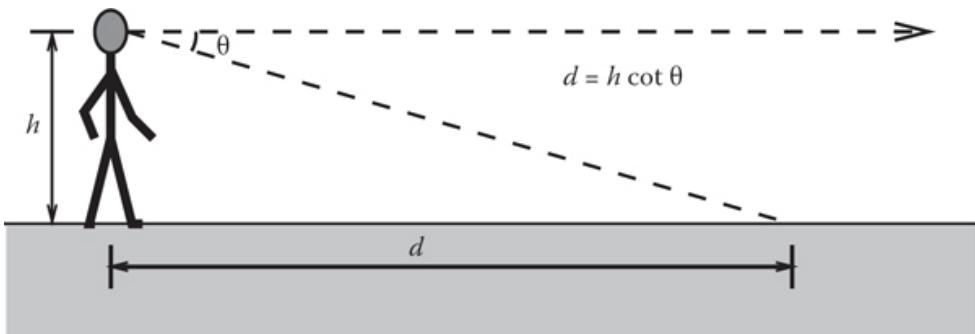

# Height in Plane

Distant objects tend to appear higher than closer objects

# Angle Declination

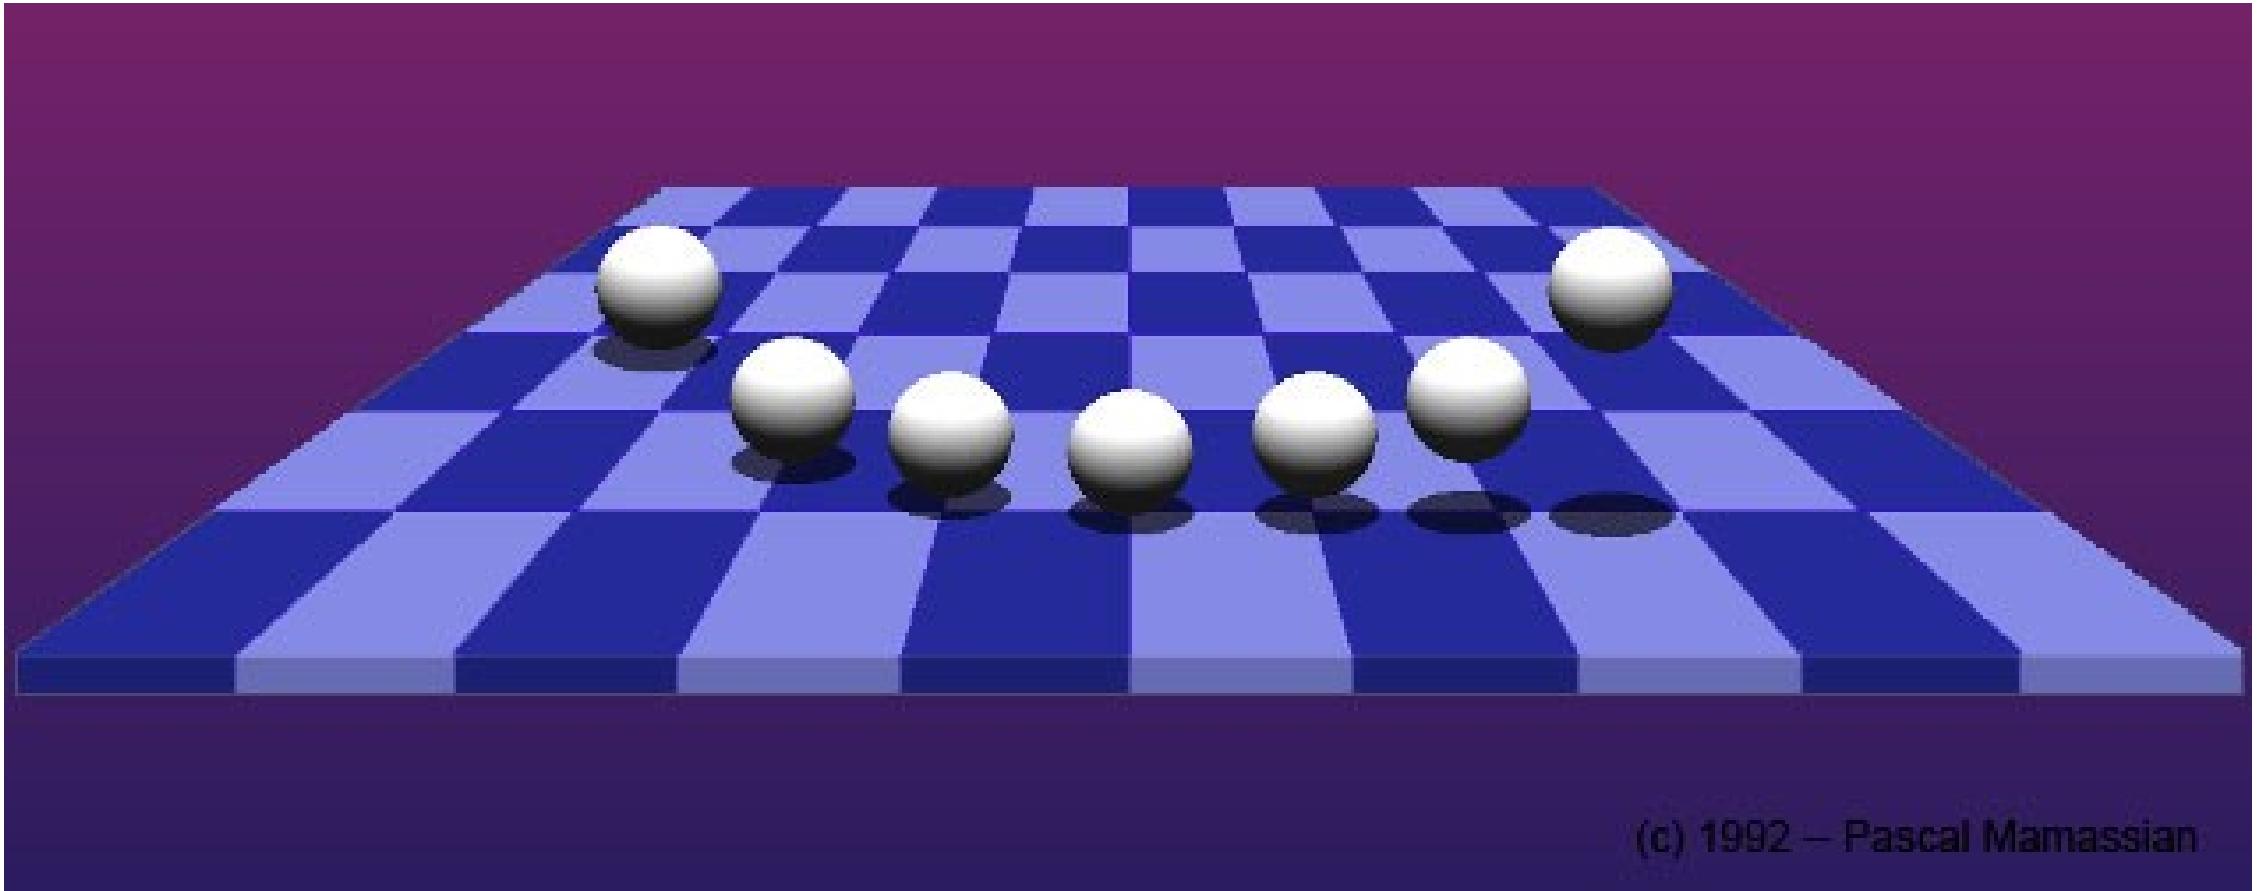

The farthest something is, the closest it appears to the centre

# Clarity

# Light and Shadow

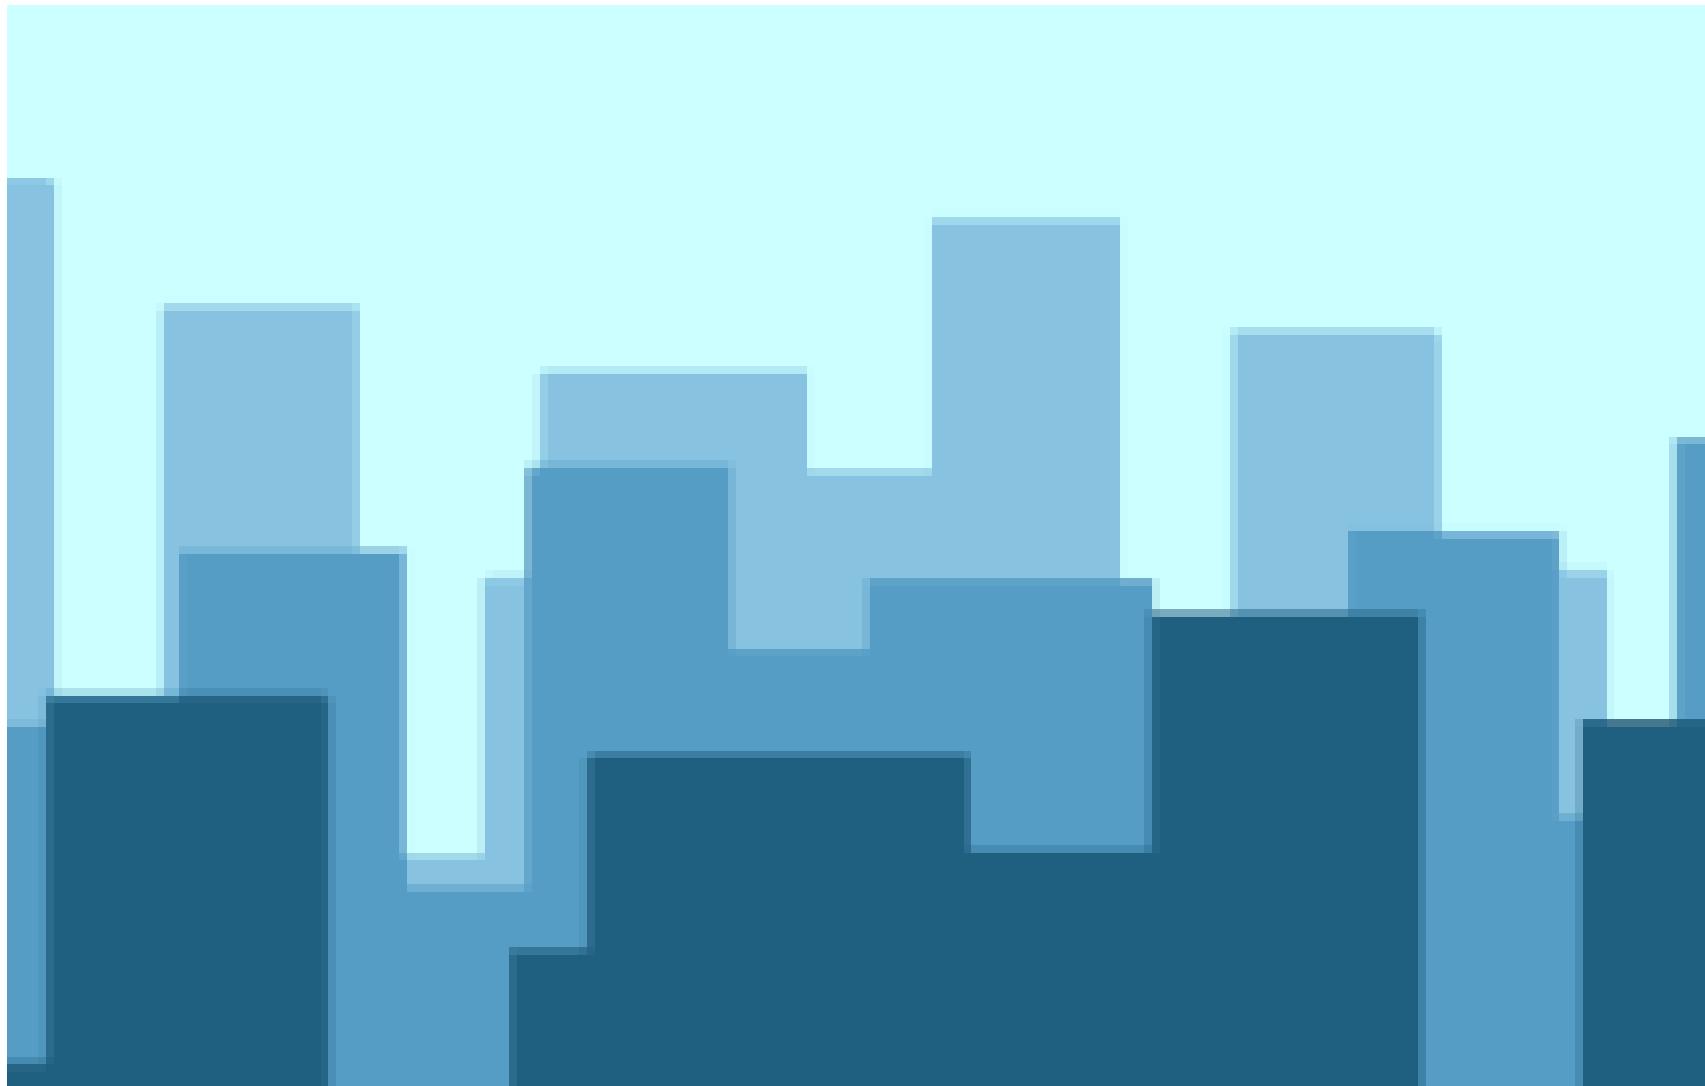

(c) 1992 — Pascal Mamassian

# Light and Shadow

Just adding colour  
does not add much  
to the shape  
perception

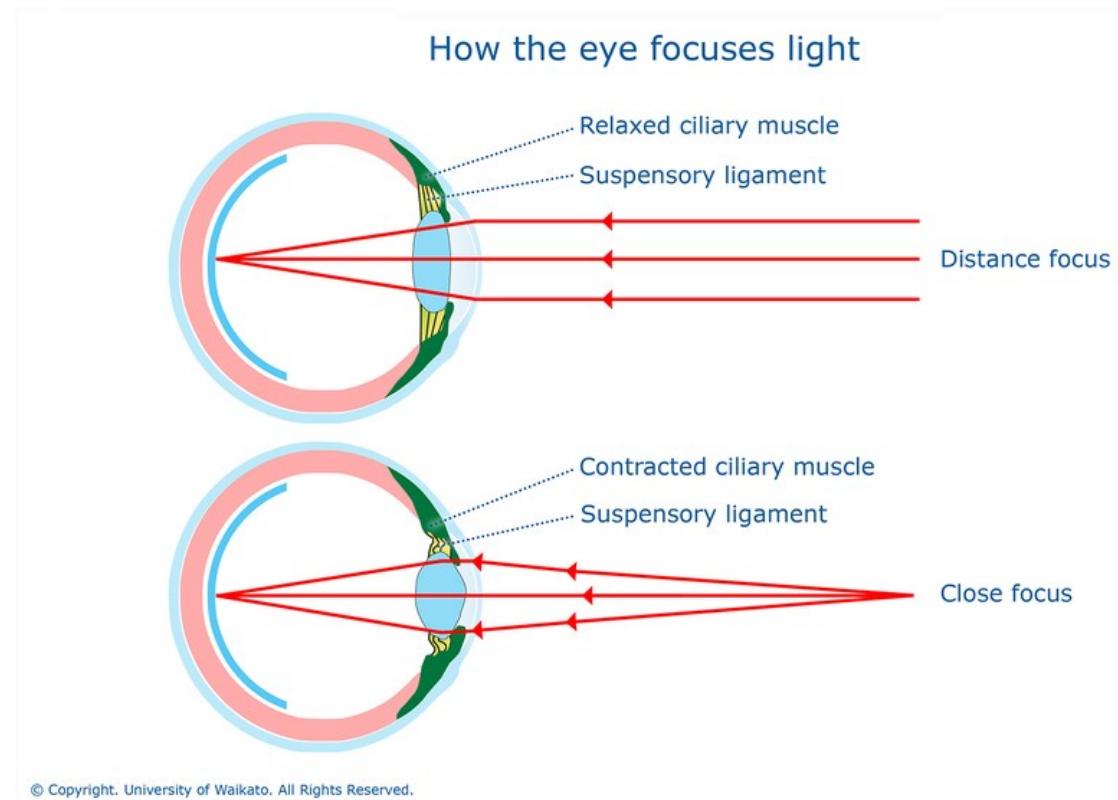

# Motion-based Motion Parallax

# Depth Perception – Accommodation

Relies on lens deformation information to focus on the target

Not a very strong depth cue and works up to around 2 m

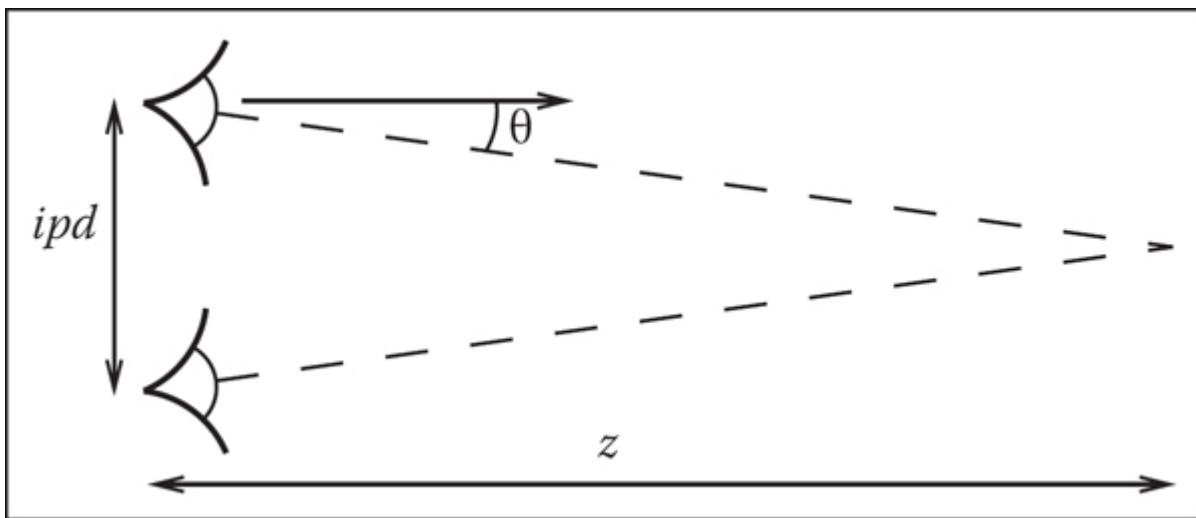

A photograph of a wooden boardwalk in a dense forest. The boardwalk is made of light-colored wood and has railings on both sides. The surrounding trees are tall and covered in thick green moss. The perspective of the boardwalk leads the eye into the distance, creating a sense of depth.

# Depth Perception

Binocular Cues

# Depth Perception - Convergence

Based on the angle of eye orientation to attain convergence at the object

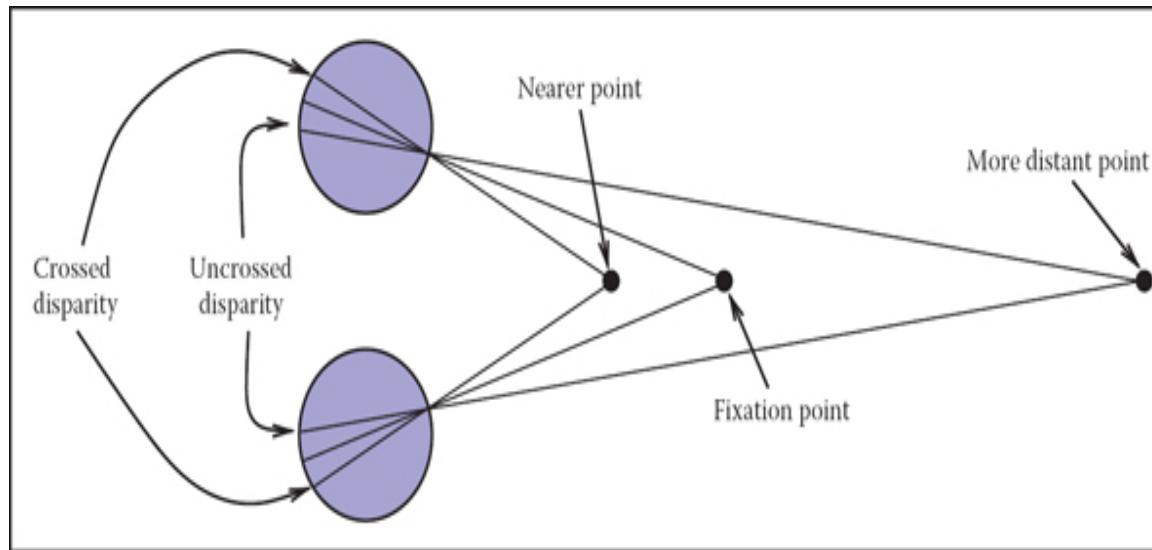

Thumbs Up  
Experiment. Again!

Binocular disparity

# Depth Perception – Binocular Disparity

# Binocular Disparity

## Anaglyph 3D

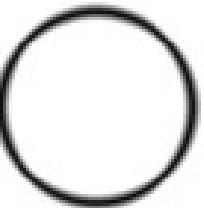

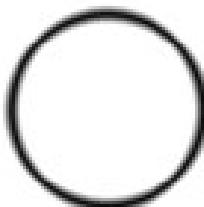

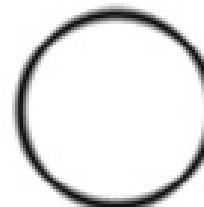

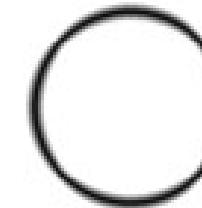

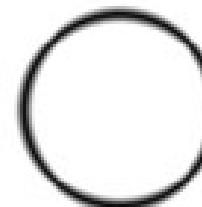

Anaglyph 3D, possible by using red-blue glasses enables watching movies in 3D by simulating the binocular disparity effect

<https://www.youtube.com/watch?v=e00N024D7Lg&t=305s>

# Stereo Vision

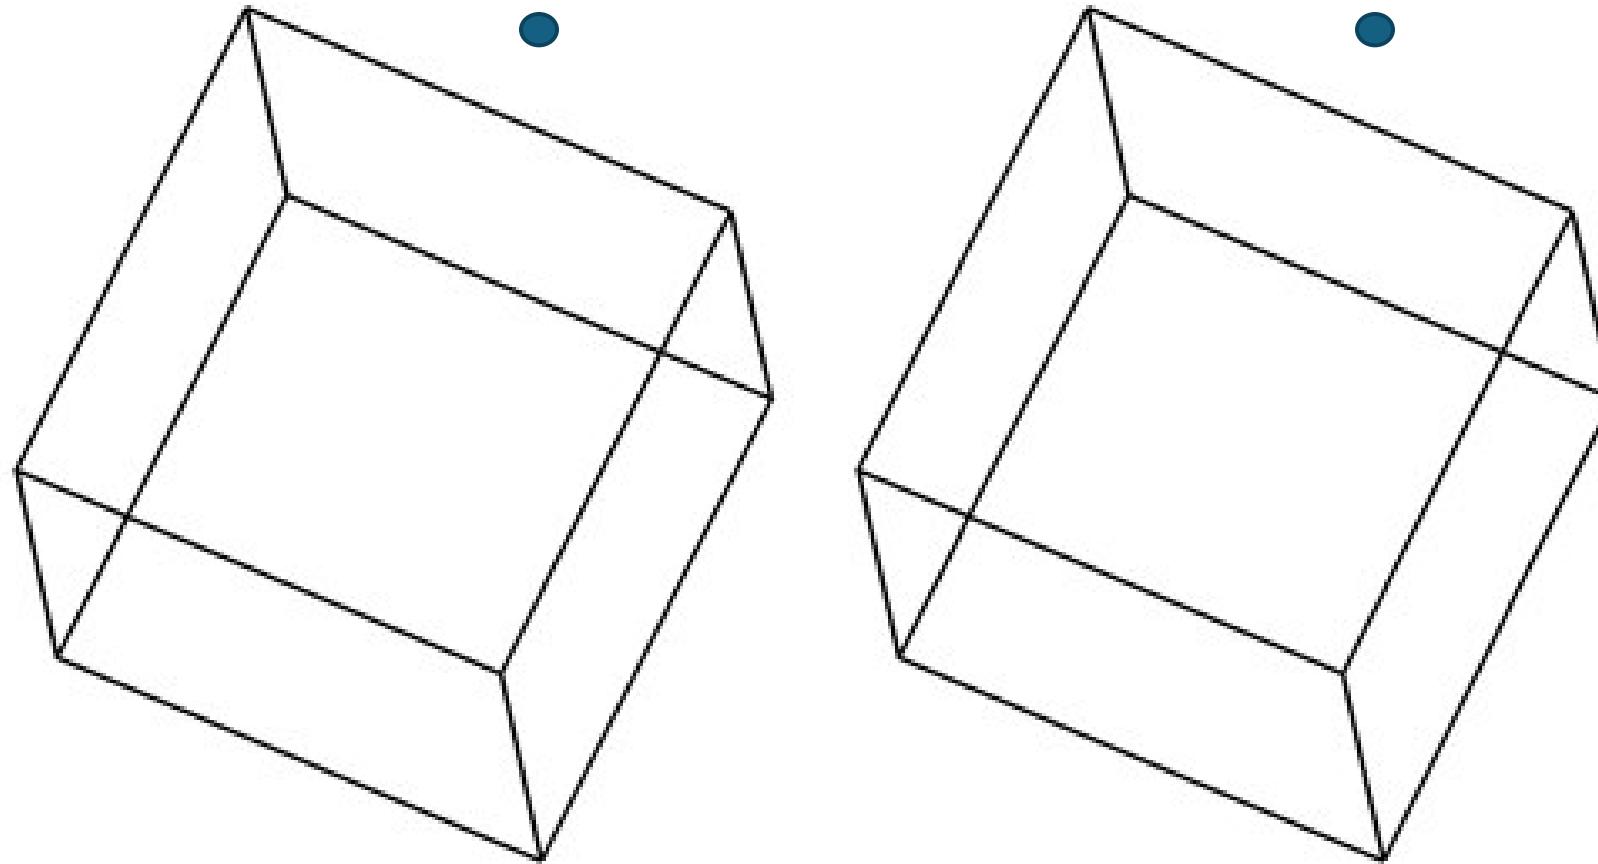

What makes us see in 3D?

Which circle is closer to you?

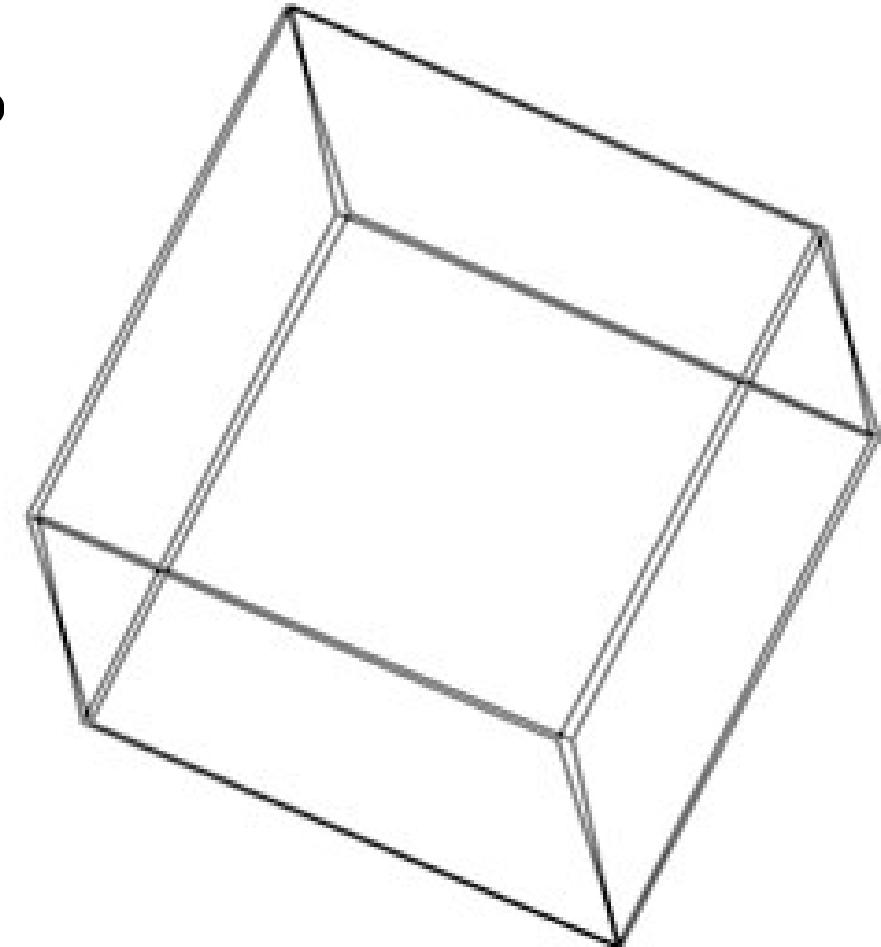

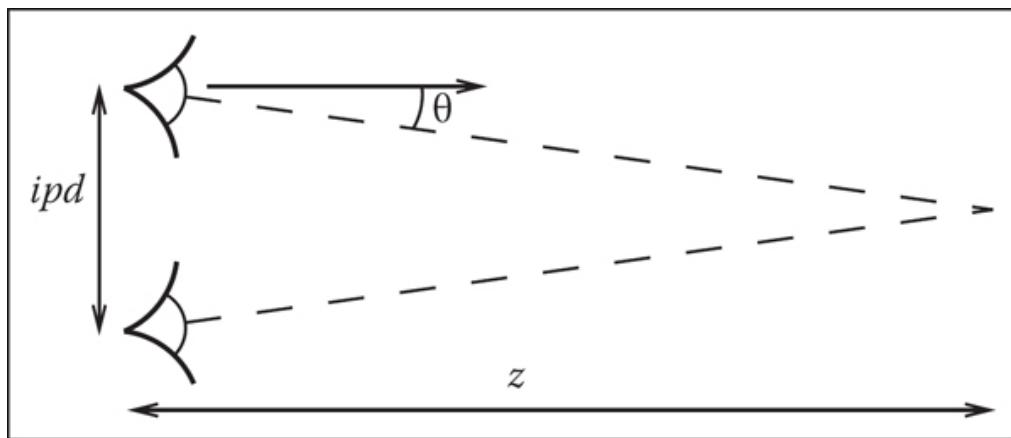

[http://steipe.biochemistry.utoronto.ca/abc/index.php/  
Stereo\\_vision\\_practice](http://steipe.biochemistry.utoronto.ca/abc/index.php/Stereo_vision_practice)

# Stereo vision

# Stereo Vision

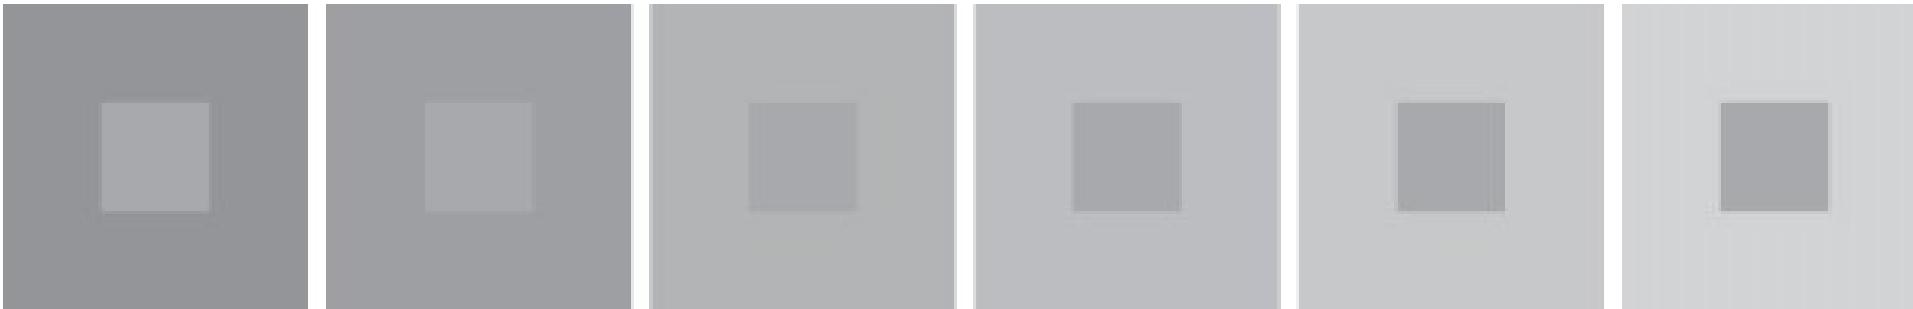

The two cubes have subtle differences to appearance to each eye

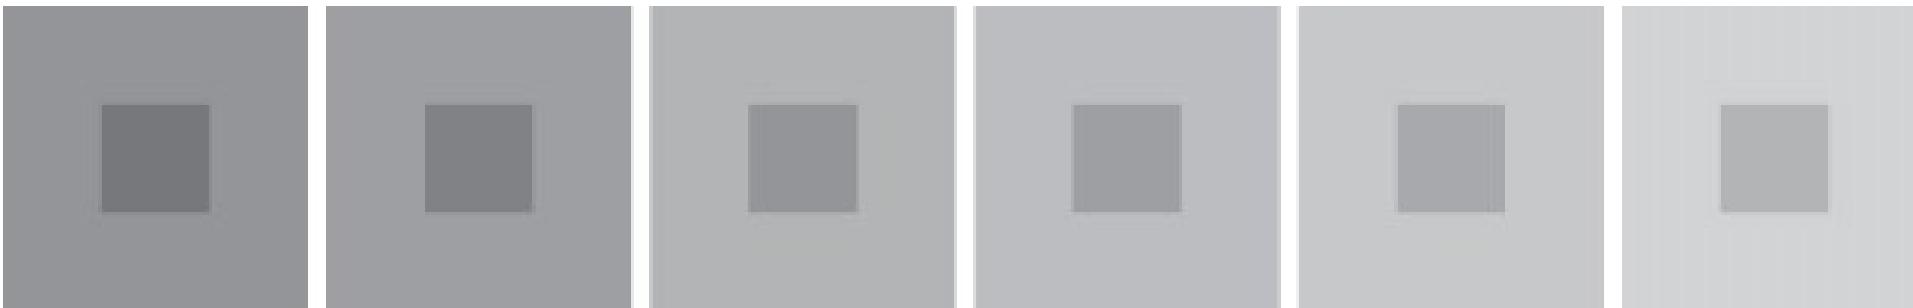

# **Constancy**

# Colour Constancy

Really bad at perceived brightness (affected by changing context)

Really good at keeping the lightness constancy under varying illumination

# Color Constancy

# Shape Constancy

- What is the shape of the table?
- Despite how it looks, we instantly know its true shape

# Size Constancy

While we see small people, we instantly know that it is because they are at a distance

<http://poshaylapsych15.blogspot.com/2014/11/perceptual-constancies-size-constancy.html>

<http://psychapprentice.weebly.com/psychology-lexicon/visual-constancy>

**Apparent interaction messes the effect**

A dynamic photograph of a dancer in motion on a city street at night. The dancer, silhouetted against a bright light source, is captured in mid-air with arms outstretched. The background is filled with streaks of light from passing vehicles, creating a sense of speed and blur. The scene is set on a wet street reflecting the city lights.

# Motion Perception

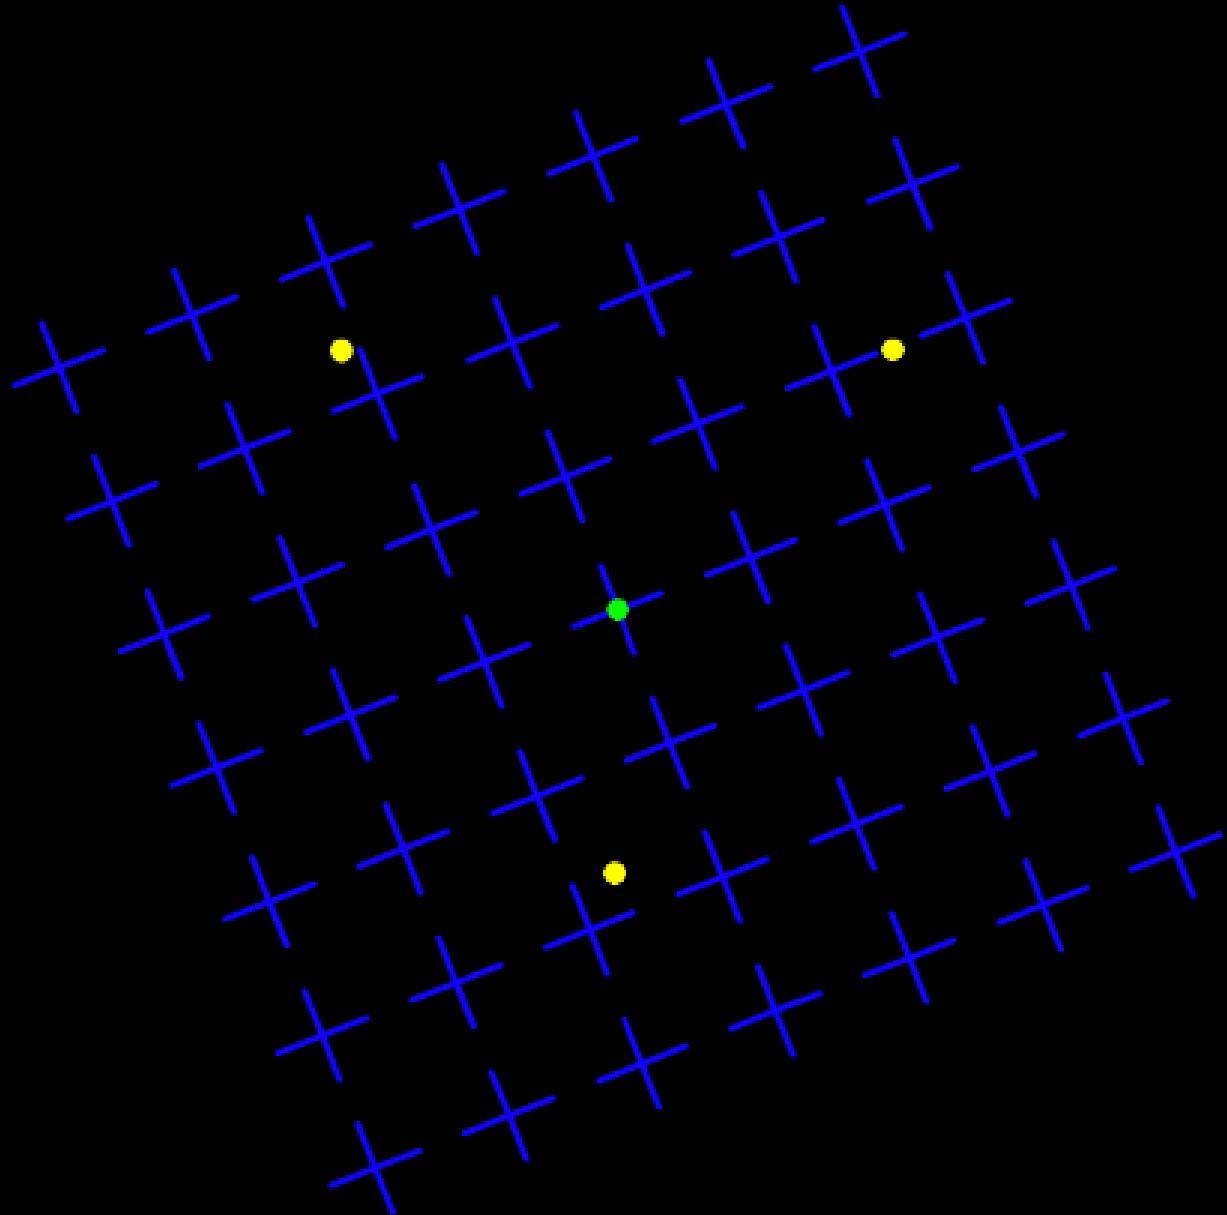

# Motion

Our visual system is particularly good at detecting motion or changes in optical flow

So, it can be an important clue to attract the eye... or to distract it

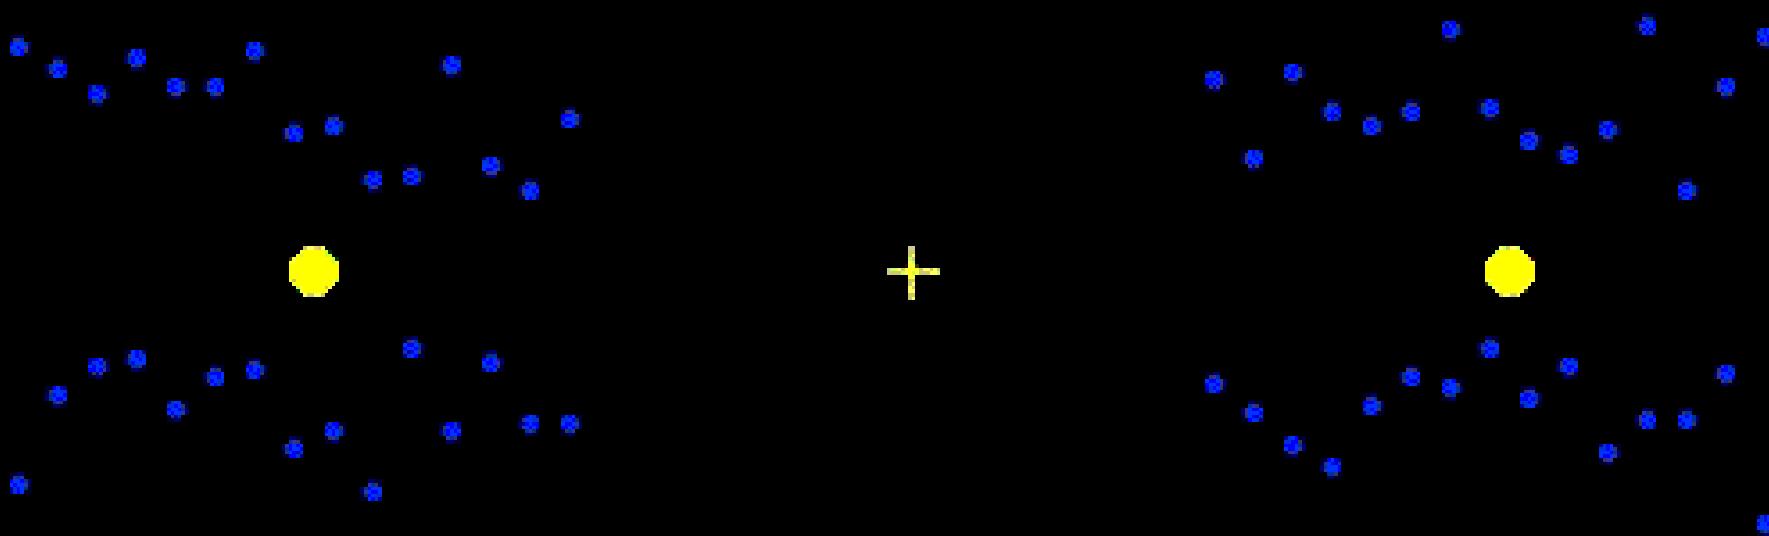

A blurred photograph of a city street. In the foreground, several people are walking away from the camera, their figures and the surrounding environment streaked with motion blur. The buildings in the background are large, multi-story structures with classical architectural details like cornices and arched doorways. A few people are standing outside, and a bus is visible on the street.

Blur as a cue for  
motion

Motion induced  
blindness

Motion induced  
blindness

# Perception of human movement

Our visual system is particularly sensitive to motion corresponding to human movement

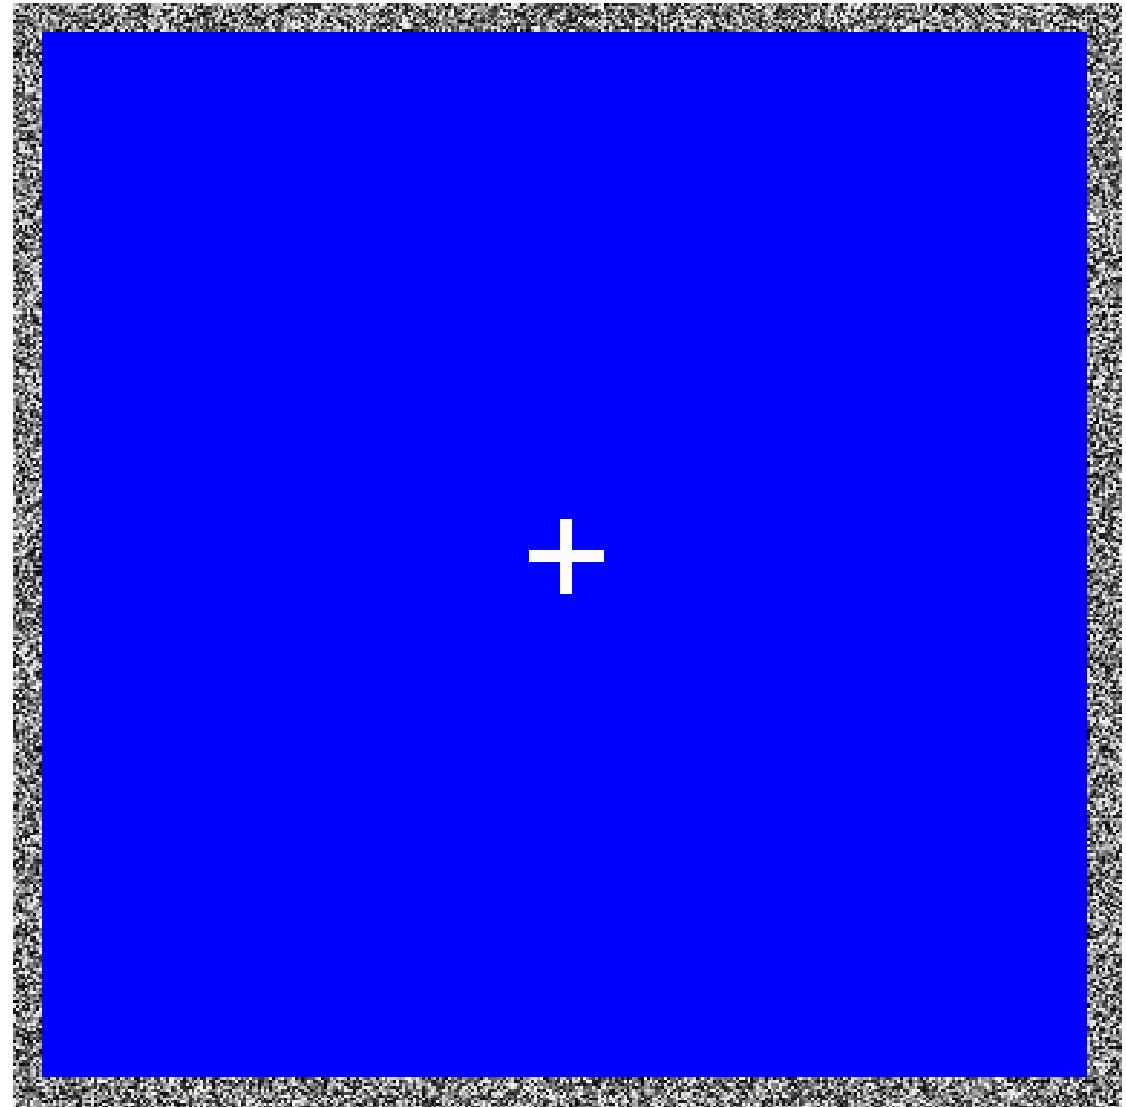

Rendering human motion is particularly challenging. Viewers will recognize even the smallest inaccuracy

# **Unconscious Perception**

## Continuous Flash Suppression

Enables showing something without the person being conscious of it  
(see it with anaglyph glasses)

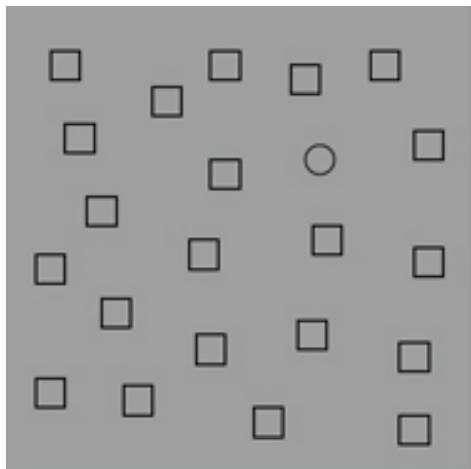

# Visual Salience and Search

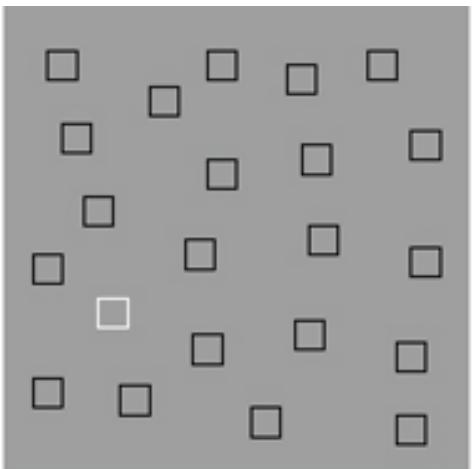

# Visual Attention

Attention processes can affect vision

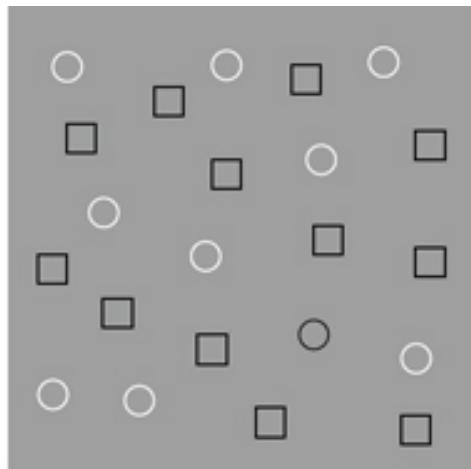

The “elephant in the room” pops out, in each of the images, but **not as fast in the rightmost image**. Why?

(a)

(b)

(c)

Attentional processes can be used to direct the user and communicate something quickly

But, they can also divert attention from what is important...

Complexity can slow down detection due to increased cognitive demand

# Visual Salience

When we first look at a scene, there are certain regions that grab our attention. They are **visually salient**.

A

B

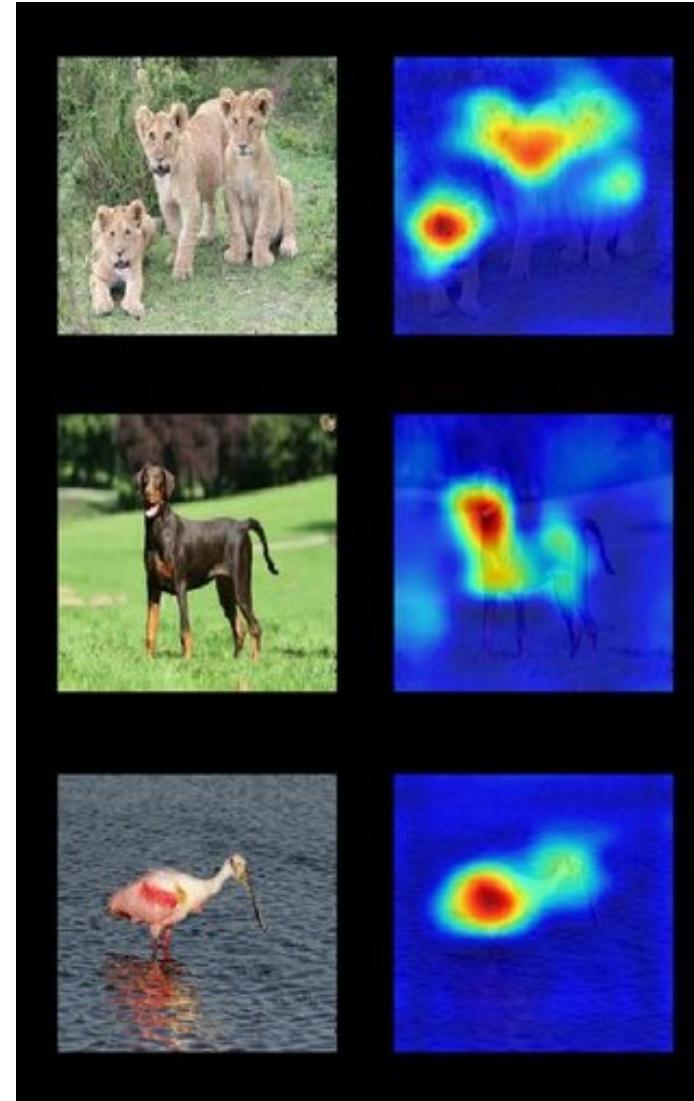

Gaspelin & Luck, 2008

# Visual Salience

Knowing / predicting the most probable visually salient regions can help focus higher rendering quality on those spots

This may be done using models of visual salience or...

**...any technology you think could help, here?**

# Visual Salience

Guiding the player

© 2022 Guerrilla

HORIZON  
FORBIDDEN WEST™

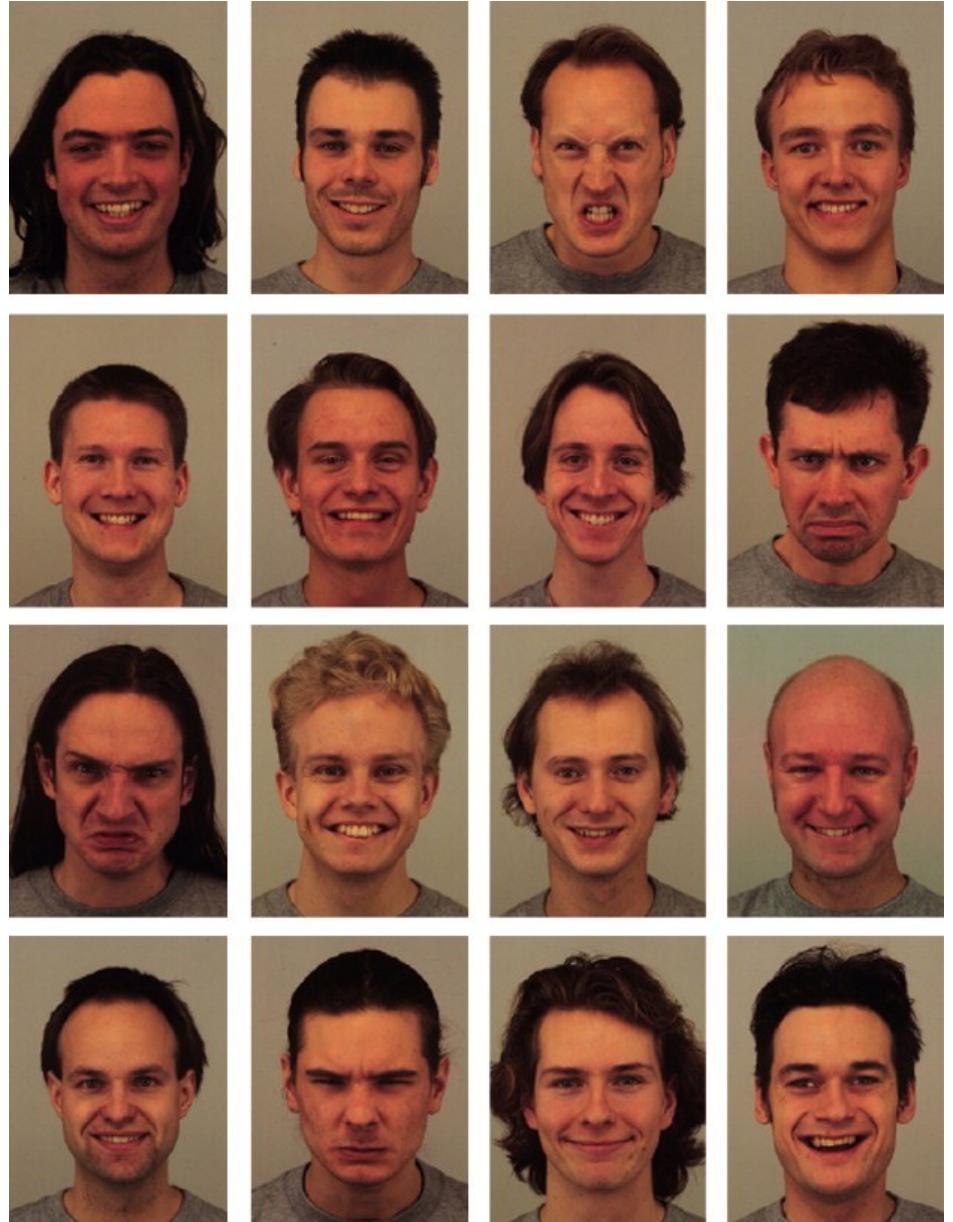

# Emotional Saliency

Given the importance of **emotion** in our daily lives, our visual system provides some advantages for processing it

A region inducing/representing a negative emotional state (e.g., angry face) can attract our eye, surpassing visual salience

Remember about snake detection early in this class!

An angry face on an NPC draws attention to it faster

KDEF database

A classic cartoon scene from "The Road Runner and Wile E. Coyote" series. On the left, a blue and purple woodpecker with a large crest and a yellow beak is perched on a branch, looking towards the right. On the right, a brown coyote with a long neck and a large mustache is running towards the left, looking back over his shoulder with a worried expression. The background is a bright yellow sky with white clouds.

**That's all, for today,  
but there is more...**
